Preface to the Second Edition

The response to the *Encyclopedia of Food and Agricultural Ethics* was so overwhelming that the editors at Springer approached Paul Thompson and me and asked if we would edit a second edition with expanded online access. Paul handed the reins to me and, in no time, nearly over 100 new entries were added. Many of the new entries add to the scope and breadth of the encyclopedia by addressing important but often overlooked topics, such as indigenous foods, fake meat products, food financialization, and pet vegetarianism. Other new entries make up for important topics missing from the first edition, including farmworker rights, food sovereignty, agroecology, and agrarianism. With this second edition, we have a chance to get it right and cover as many central and interesting topics as possible.

As the start of the twenty-first century has seen intensified discussion and criticism of food and agriculture around the world, the second edition of the *Encyclopedia of Food and Agricultural Ethics* aims to provide an overview of timely and pertinent issues. Scholars, activists, and citizens increasingly question the goals and ethical rationale behind production, distribution, and consumption of food, as well as the use of crops for fuel and fiber. These food and agricultural issues are also bound up with issues of governance, trade, culture, and religion. The issues are of local, national, and international concern; the debates are wide-ranging and the decisions affect everyone. The *Encyclopedia of Food and Agricultural Ethics, Second Edition* aims to be an indispensable reference point for research, writing, and discussion about the ethics of food, agriculture, animals, and eating.

David M. Kaplan
Editor-in-Chief

Preface to the First Edition

When we met with our coeditors and representatives of Springer in May 2010 to begin conceptualizing the *Encyclopedia of Food and Agricultural Ethics*, we were thinking along the lines of something that would be a cross between a traditional general-interest encyclopedia and a “handbook.” We envisioned a work that would help scholars and relatively advanced students obtain a quick introduction to the issues and the published literature that was most relevant to a broad range of issues in the ethics of food and agriculture. We took “ethics” to imply thoughtful and scholarly studies on the normative dimension of topics rather than rubrics or remonstrations on right action. We wanted to create a resource for those interested in learning more about the ethical dimension of food and agriculture rather than a collection of arguments for particular ethical positions.

All areas in practical ethics suffer from a deep ambiguity of this kind. On the one hand, for many people, ethics simply implies an uncomplicated matter of doing the right thing. “Being ethical” would be understood in contrast to blatantly unethical actions such as the intentional contamination of Chinese milk products (including infant formula) with melamine in 2008. No one needs scholarly research to understand why this action was unethical, just as no one needs philosophy to explain why it is wrong to leave farm animals to suffer and die from a lack of feed and water. On the other hand, the circumstances that lead to these blatantly unethical actions can be better understood (and hopefully prevented) through careful research on the institutions and incentives faced by human actors. Ethical analysis can shed light on how ethical situations come about and what we might do in response.

In addition, there are some topics whose ethical dimensions are less obvious such as biofuel production and international trade regulations. These topics require careful research and analysis to reveal the ethical issues. Sometimes, they are beset with contradictory and conflicting views on why and even whether issues of right and wrong are involved at all. It is these case examples that give rise to scholarship by philosophers, social scientists, and agricultural specialists. The *Encyclopedia of Food and Agricultural Ethics* was conceived to provide overviews of the work that had already been done on key areas of practice in food and agricultural systems of production, distribution, and consumption. The aim was to facilitate more and better scholarship in all aspects of the field.

And so, we entered the project with the expectation that it would be a long and arduous process to recruit authors and to compile a volume of the scope

that the subject deserved. The volume that emerged has met our expectations in many respects; yet, there are two ways in which the original vision has been significantly altered.

First, many of the topics that we placed on the original list had far less existing scholarship than we expected. There is still a lack of scholarly maturity in the field of food and agricultural ethics. The problem we faced is that an encyclopedia is a work of tertiary literature. It should contain neither research (primary literature) nor review articles summarizing original papers (secondary literature). It should instead summarize established information in the field. As editors, we found ourselves in the unfortunate position of too little to edit. Worse, we had to exclude fine works of original ethics scholarship more appropriate for a journal such as Springer's *Journal of Agricultural and Environmental Ethics* than for a reference work. It is our hope that today's original scholarship on food and agricultural ethics will soon develop a secondary literature that deserves its own encyclopedia entry.

Second, the continued growth of digital publishing has shaped our editorial practice in ways that we did not fully anticipate. While electronic access was a crucial aspect of the original design, we did not fully appreciate the impact of this format on the timeliness of content. As the first entries began to trickle in during 2011 and 2012, we began to realize that the pace of scholarship (and of the issues themselves) threatened to date some very fine entries by the time that the entire edition would be done. It became clear that the cutoff date for declaring the encyclopedia to be "complete" and ready for publication was becoming increasingly arbitrary. At the end of the day, we decided that it was more important to go to press than to cause further delay in making the fine work that we had already compiled available. Entries will continue to be added, and existing entries will be updated in the online edition. The *Encyclopedia of Food and Agricultural Ethics* will be a living document.

August 2014

Paul B. Thompson
David M. Kaplan

List of Topics

- Absentee Landlords and Agriculture
- Access to Food
- Access to Land and the Right to Food
- Aesthetic Value, Art, and Food
- Africa, Food, and Agriculture
- Agrarianism and the Ethics of Eating
- Agricultural and Food Products in Preferential Trade Agreements
- Agricultural Coexistence
- Agricultural Cooperatives
- Agricultural Ethics
- Agricultural Science and Ethics
- Agricultural Science and Values
- Agricultural Sciences and Ethical Controversies of Biofuels
- Agricultural Subsidies: Ethical Issues
- Agriculture and Colonialism
- Agriculture and Ethical Change
- Agriculture and Finance
- Agriculture of the Middle
- Agroecology
- Alcohol Abstinence and Sobriety
- Alcohol as Food and the Good Life
- Alimentary Delinquency
- Alternative Food Networks
- American Agrarianism
- American Chestnut and De-extinction Ethics
- American Cuisine, Existence of
- American Food Rhetoric
- Ancestral Cuisine and Cooking Rituals
- Animal Agriculture and Welfare Footprints
- Animal Boredom
- Animal Welfare in the Context of Animal Production
- Animal Welfare: A Critical Examination of the Concept
- Aroid Production and Postharvest Practices
- Artisanal Food Production and Craft
- Asian Cuisine: Ethical Considerations
- Authenticity in Food
- Beef Production: Ethical Issues
- Beekeeping and Agriculture
- Biodiversity
- Biodiversity and Global Development
- Biodynamic Agriculture
- Biofuels: Ethical Aspects
- Biopharming
- Biosecurity and Food Systems
- Biotechnology and Food Policy, Governance
- Biotechnology for Environmental Purposes
- Body Image, Gender, and Food
- Brazilian Agriculture
- Brillat-Savarin and Food
- Buddhism, Cooking, and Eating
- Buddhist Perspectives on Food and Agricultural Ethics
- Canada, US-EU Beef Hormone Dispute
- Canadian First Nations and Food
- Cannibalism
- Carbon Farming
- Care Ethics and Food
- Carnism
- Child Nutrition Guidelines and Gender
- Chinese Agriculture
- Chocolate: Ethical Dimensions
- Christian Ethics and Vegetarianism
- Christian Mysticism and Food

About the Editor-in-Chief

David M. Kaplan is associate professor in the Department of Philosophy and Religion at the University of North Texas. He is the author of *Food Philosophy* (Columbia University Press), editor of *The Philosophy of Food* (University of California Press), and coeditor with Paul B. Thompson of the *Encyclopedia of Food and Agricultural Ethics, First Edition* (Springer). He has published articles on food technologies, genetically modified food, artificial ingredients, and junk food. He also manages the *Philosophy of Food Project*: www.food.unt.edu.

Absentee Landlords and Agriculture

Peggy Petrzelka

Department of Sociology, Social Work and Anthropology, Utah State University, Logan, UT, USA

Synonyms

[Absentee landlords](#); [Absentee landowners](#); [Farmland ownership](#); [Female landowners](#); [Landlord-tenant relationship](#)

Introduction

Absentee landlords of agricultural land do not live on their land but lease it to others to farm. These can include retired farmers and ranchers, individuals who inherit land but live elsewhere, and those who buy land for recreational or investment purposes and reside elsewhere (Petrzelka et al. [2013](#)).

An “unprecedented level of absentee ownership” of rangelands has occurred in the US West (Haggerty and Travis 2006, p. 825); and in the Midwest, an increasing number of farmland owners are no longer living on their land or even in the state where their land is located (Duffy and Smith 2008). However, no nationwide data set exists on this growing group of agricultural landowners, and little research exists about differences between residential landlords (who reside on the land) and absentee landlords (who reside elsewhere). Absentee ownership and absentee landlords of agricultural land are major issues that are poorly understood, yet have ethical, social, and environmental implications.

This entry discusses absentee landlords in the larger context of US agricultural land ownership. Trends in US agricultural and absentee landownership as they relate to rented farmland are first examined. Then, an overview of research on agricultural landlord-tenant operator relationships is presented, discussing both resident and absentee landlords and incorporating ethical, social, and environmental implications which may occur with the landlord-tenant relationship. The entry provides suggestions for future work on the topic of absentee landlords and concludes by providing information on organizations working with absentee landlords.

Overview of US Agricultural Ownership

In the early twentieth century, most rented farmland in the United States was operated (i.e., farmed) by full tenants (who owned none of the land they operated), reflecting in large part the legacy of plantation agriculture in the south, with many former slaves working as sharecroppers for white landowners. The Great Depression and World War II brought the collapse of full tenancy and sharecropping. Since that time, a growing share of US farmers are part owners, who rent in addition to own land they farm (Jackson-Smith and Petzelka forthcoming).

Figure 1 illustrates that the overall proportion of land that is operated by the owner in the United States has not changed dramatically over time.

What has changed is the proportion of land that is owned and operated by part owners. Approximately 922 million acres of US farmland (42% of the Nation’s land base) was operated in 2007 (U.S. Census of Agriculture 2012). Thirty-seven percent of this land was operated by full-owners (i.e., they own all the land they operate). Part owners comprised one-quarter of US farms, owned slightly less than half of the total land they operated, and dominated the market for rented farmland. Their importance in the US farm sector increased rapidly from the 1920s through the early 1980s and has remained relatively constant since then. Currently, full tenants comprise just 6% of farms and operate 9% of farmland.

Figure 2 shows the proportion of US farmland rented or leased by county, according to the 2007 Census of Agriculture. There is a general tendency for many of the most commercially important agricultural areas to see higher rates of land leasing (Nickerson et al. 2012). As evidenced, several geographic regions (including the Midwestern corn belt, Great Plains wheat region, Central Valley in California, Lower Mississippi Delta, and Atlantic Seaboard) have a majority of farmland that was operated by someone other than the owner. These variations in rates have been explained in part by laws in some states that limit farmland ownership by corporations, non-farmers, or non-US residents (Nickerson et al. 2012).

The US Census of Agriculture does not collect data from agricultural landlords. However, national trends on agricultural landlords have been collected by the Agricultural Economics and Land Ownership Survey (AELOS), conducted by the National Agricultural Statistics Service of the US Department of Agriculture (USDA). AELOS collects information from both landowners and tenants and is the only nationwide source of information about agricultural landlords. The most recent AELOS survey was conducted in 1999. Findings show only 13% of individual (or partnership) landlords lived on the farmland that they rented out (i.e., were resident landowners rather than absentee). While about a third of these landlords lived on some type of

Absentee Landlords and Agriculture, Fig. 1 Total acres and percent of acres by operator tenure status. (Source: US Census of Agriculture, various years)

farm, the largest group reported residences in cities, towns, or urban areas. This urban group provided nearly 45% of the total rented acreage reported in the 1999 AELOS. Demographically, most private farmland landlords were relatively older – over half were over 65 and these individuals provided 50% of all leased farmland in the United States. Most private landlords also reported jointly owning their farmland, and female landlords were likely to lease out more of the land they own (Jackson-Smith and Petrzela forthcoming).

The AELOS has been conducted only twice (in 1988 and 1999), and therefore, it is difficult to infer trends or derive information about current agricultural landlord patterns. More detailed and recent data come from smaller geographies. For example, the Iowa Land Ownership Survey has collected panel data from a representative state-wide sample of land parcels and landowners in Iowa since 1949 (Duffy and Smith 2008). (Data has been collected in 1949, 1958, 1970, 1976,

1982, 1992, 1997, and 2002). While national trends suggest that the total proportion of farmland that is owner-operated land (thus not rented) has hovered near 60% since World War II, the Iowa study shows a pronounced decline in the proportion of land under owner-operator status (dropping from 55% in 1982 to 40% in 2007). Scholars who have conducted research on absentee landowners in small geographic pockets speculate that this decline in owner-operator status is partly because of the aging of the farmland owner population. For example, in Iowa, the share of land owned by persons over 65 increased from 29% in 1982 to 55% in 2007 (Duffy and Smith 2008). This change is also reflected in the increased importance of older female agricultural landlords across the Midwest (Petrzelka and Marquart-Pyatt 2011).

Based on the limited research and data on absentee landowners of agricultural land, it appears the majority of these landowners fall under the category of nonoperator owners. These

Absentee Landlords and Agriculture, Fig. 2 Percent of land in farms rented or leased in 2007. (Source: 2007 Census of Agriculture, Agricultural Atlas Maps; Available

online at: http://www.agcensus.usda.gov/Publications/2007/Online_Highlights/Ag_Atlas_Maps/Operators/Tenure/07-M117.php)

nonresident landowners, as compared to those living on the land, are much more likely to live in urban areas, less dependent financially upon the land, and much more likely to own land for amenity reasons (e.g., recreation, vacationing) than production purposes (Petrzelka et al. 2009; Petrzelka 2012).

Overview of Agricultural Landlords: Resident and Absentee

With the large amount of farmland rented, the landlord-tenant relationship clearly plays a significant role in US agriculture. The few empirical studies on the landlord-tenant relationship in the

United States mainly focus on resident landlords and show that tenants often have substantial managerial control over the land. For example, Gilbert and Beckley (1993) studied decision making in two Wisconsin townships and found landlords and tenants in agreement that the tenants were the primary decision makers for operational decisions on the farm such as types of commodities to grow, application of particular soil conservation practices, and participation in specific federal programs.

Effland et al. (1993) examined landlords' involvement in farm management decisions using the 1988 AELOS data and historical documents and found that female landlords were less likely to make farm management decisions than

male landlords and were more dependent on the farmland for income. In addition, women were more likely to have inherited their farmland and tended to be older than male landlords. Also using the 1988 AELOS data, Rogers and Vandeman (1993) found those landlords who were more involved in decision making had past farming experience, lived closer to the land, and rented on a crop-share basis (wherein typically landlord and tenant share management decision making, risks, and benefits) rather than a cash rent basis (wherein tenant pays rent for use of the land, typically makes all management decisions, incurs all risk, obtains all benefits). Rogers and Vandeman (1993) also found that female landlords were less likely than male landlords to participate in choices of fertilizer and chemical practices on leased land and that younger landlords, both male and female, were more involved in on-farm management decisions, as were those who identified themselves as farmers.

Constance et al. (1996) were the first to analyze both resident and absentee landlords in their Missouri study of landlords' involvement in decision making on rented agricultural land. Decision making focused on crops grown, tillage practices, types of pesticides, pesticide application, and participation in soil conservation and water quality programs. The researchers found resident and absentee landlords were most likely to be involved in conservation program decisions, least likely to be involved in pesticide decisions and overall, and less involved in all of the decision-making practices. Focusing more specifically on predictors of landlord involvement in pesticide selection, Constance et al. (1996) found among resident landlords that being male, having a higher dependence upon the farmland for income, and having a farming background were the most significant factors predicting involvement. For absentee landlords, the distance the landlord lived from the land was a predictor (where those living closer were more involved) as was a higher dependence upon the farmland for income and age; with younger landlords more involved, the researchers argued, possibly due to their increased environmental consciousness.

While many landlords and tenants in Gilbert and Beckley's (1993) study reported they were very satisfied with the landlord-tenant relationship, the researchers argue (1993, p. 578) that in some instances, the tenants appeared to be exploiting their landlords, who are often "retired farmers, small landowners, and widows."

This potential exploitation resulting from the landlord-tenant relationship is evidenced in studies from Iowa. In a study of resident and absentee landlords, Eells (2008) found deception of female landlords occurring with some tenant relationships. This deception occurred particularly in terms of potential soil conservation measures, which would be presented to the female landlord by the male tenant most often in "an authoritative way as not being very practical or effective" (p. 67). Wells (2003) found maintaining peace in the family overrode preferences on conservation decisions for female resident and absentee landlords, particularly when ownership of the land was shared with family members and even more so when the tenant was also a family member. Female agricultural landlords interviewed noted the difficulty in sharing ownership with siblings as many decisions were made in order to keep peace in the family, and self-censorship by female landlords occurred with their male relatives and tenants. Carolan (2005, p. 396) also found self-censorship would occur by female landlords in Iowa who were reluctant to discuss implementing sustainable agricultural practices on their land with their tenants, fearing they would "scare away good tenants." Carolan (2005, p. 402) stated, "all of the female landlords described inequitable power relations between themselves and their male tenants. Specifically, they expressed feelings of exclusion [and] alienation [from the farm decision making]."

Expanding this research beyond Iowa, a 2011 study of landlords in four Great Lakes counties (Petrzelka and Marquart-Pyatt 2011) found female absentee landlords are less likely to be involved in decision making on their land if they are older, when their financial reliance on the land is greater, if they are retired, if they inherited the land, when they co-owned the land with a sibling, and when a local farmer was their tenant. For male

absentee landlords, involvement in decision making on their land is reduced only when a local farmer farms the land. Thus, the subordinate landlord-dominant tenant possibility suggested by Gilbert and Beckley in 1993 appears to be occurring most frequently with female landlords.

Issues and Implications of Absentee Landownership

In 1993, Rural Sociologist Gene Wunderlich noted, "The change in the structural relationship between farming and land ownership implies potential changes in who bears risk, makes production and investment decisions, protects the environment, and supports the community. Who, between farmer and landowners, decides whether farmland will go into a conservation reserve? Are non-operator owners less risk averse in production decisions than operator owners? Are absentee landowners as concerned about pesticide contamination of drinking water as resident owners? How are school budgets and community facilities affected by the level of absentee taxpayers?" (1993, p. 549).

The issues and implications Wunderlich posed in 1993 are even more relevant today. Those highlighted here include land management decision-making authority, agri-environmental behaviors, and impacts on local community well-being.

In general, the minimal research on resident and absentee landlords has consistently found that landlords of agricultural land allow their tenants to make operational decisions and that female landlords are less involved in decision making regarding land use compared with males. When looking specifically at involvement in conservation decision making, female landlords were much more likely to censor themselves, particularly when they co-owned the land and their tenants were family members. While a growing share of farmland owners are women, primarily widows (Duffy and Smith 2008), female landlords may still find themselves in a disadvantaged position because of patriarchal structures in rural communities.

The handful of studies which exist consistently suggest a power relationship between landlords and tenants. Contemporary research that explores how this power relationship is mediated by social relationships (gender, families, race or ethnic identity, and other direct social ties) and geography could both assist organizations working with absentee (and resident) agricultural landlords, as well as help advance social theories of ownership, rent, and power (Jackson-Smith and Petrzalka forthcoming).

A second power issue is based on changes in the structure of agriculture and the relative availability of agricultural land. As demand for farmland increases because of rising global commodity prices, and where available prime land required for commercial agriculture in the U.S. is in short supply, farm operators are forced to compete with one another to gain access to farmland. In areas with declining populations and increased consolidation of farming operations, landlords may have few options to rent out their land, which places tenants in a stronger position. In both cases, the actual relative power of the landlord and tenant is likely to be mediated by gender, family ties, and other social relationships (Jackson-Smith and Petrzalka forthcoming).

Regarding environmental implications, scholars studying the adoption of conservation practices in agriculture have often assumed that farm operators are more likely to make investments in conservation practices (particularly control of soil erosion) when they have secure long-term access to and personal ownership interests in their farmland (e.g., Featherstone and Goodwin 1993; Caswell et al. 2001). Nonoperator owners are less likely to be enrolled in USDA conservation programs such as Conservation Reserve Program (CRP) or the Wetlands Reserve Program (WRP) (Nickerson et al. 2012) consistent with research that found that tenants were less likely than owner operators to adopt conservation practices that provide benefits over the longer term (Soule et al. 2000).

In part, this can be explained by distance from the land. The farther removed physically absentee landowners are from their land, the more isolated they are from local social networks and contacts,

both of which are well-established criteria for promoting recommended land management practices. In comparison to resident landowners, absentee owners are much less likely to have personal contact with local extension and natural resource agency program staff, leading to lower levels of scientific and traditional management knowledge about local environmental conditions (Redmon et al. 2004; Petrzalka et al. 2009). Further, they are less familiar with the traditional land/farming culture and less attuned to conventional sources of information and agency.

Additionally, farmland owners without social ties to the local community may be less aware of (and perhaps care less about) the effects of land management on neighboring property owners. Yung and Belsky (2007) found that absentee owners' goals for their land, such as increased wildlife, have resulted in detrimental environmental impacts on neighboring lands, and subsequent social issues, as the economic livelihood for those depending on the land is damaged.

One of the challenges is how to engage absentee owners in the community(ies) nearest where their land is located and provide education on the collective impact of their behavior. Some local conservation groups have attempted to pair new absentee landlords and experienced ranch managers in an informal effort to facilitate exchange of information and ideas (Yung and Belsky 2007). It would be beneficial to conduct specific case studies to examine how these matchmaking efforts are working, both in terms of logistic and administrative mechanisms but also subsequent community impacts and longitudinal conservation effects on the landscape.

Additionally, there is little research on the role of absentee ownership on social issues such as community well-being, yet as absentee ownership increases, social relations in the community increasingly transcend locality. Theoretically, absentee landowners may be expected to be less engaged in community activities (because of the distance they live from the land and/or lack of strong social ties). This idea, though, has received relatively little empirical research.

It has been suggested that since some farm program payments are paid directly to landlords

of agricultural land, when a large percentage of these landlords live in urban areas, it raises questions about whether farm program payments benefit rural community economies as intended (Drabenstott 2005; Nickerson et al. 2012). One study examined the impact of absenteeism on rural community property tax revenues and found the benefits of Alabama's low property tax rates benefit absentee owners more than the local community, limiting the ability of local governments to meet citizen needs (Majumdar 2011). More studies looking at the community impacts of absentee ownership are needed.

Summary

In summary, agricultural landlords are an understudied group, absentee farm landlords even more so. At present, no nationwide data set exists on this growing group of agricultural landowners. Yet, given the changing patterns of agricultural land ownership, the power issues occurring within decision making on the land, and ethical, social, and environmental implications of absentee landownership, absentee landlords are a group we can no longer neglect.

Various organizations have begun working with these landlords. For example, the Women Caring for the Land program (http://www.wfan.org/Women_Caring.html) provides a manual for female landlords (resident and absentee) that assists women in "learning more about their rights as landowners, about best management practices, about communicating effectively with their tenants, and about state and federal cost-share and loan programs available to help them." The report can be found here: http://www.wfan.org/Women_Caring_files/WCLManualForWeb3-12.pdf. The Conservation Connect program in Iowa (<http://www.absenteelandowners.org/>) provides information to absentee landowners who are interested in natural resources conservation and who want to gain more information about available conservation programs, resources, and support. And Drake University's Sustainable Farm Lease program provides landowners a tool kit of information that, among other things, introduces "landowners to

the principle issues regarding the use of a lease agreement to promote a sustainable farm operation” and promotes “creative lease contracts that take landowner and tenant needs into consideration while enabling tenant’s to conserve farm resources” (<http://sustainablefarmlease.org/>).

Food security; Food use

Introduction

Limited access is defined by the USDA (2015) through reference to three criteria: household income, ability to make reliable use of transportation, and distance to full-service grocers. While the USDA's (2015) definition is somewhat narrow, it highlights elements that serve as a basis for a more general account of access to food. The three criteria of the USDA (2015) definition suggest that food access is a matter of wealth, ability to make use of infrastructure and resources, and how both affect an individual's or community's ability to eat a nutritionally sufficient and culturally appropriate diet (Maxwell and Frankenberger 1992).

Access to food can be contrasted to the availability of food. The availability of food is usually understood as a technical matter dependent on agricultural productivity and the efficiency of infrastructure and practices related to the transportation and processing of food. On the other hand, access to food is a social, economic, and political

matter determined by exchange entitlement, which Sen (1998) frames in terms of:

1. Trade-based entitlement: one's capacity to obtain goods through exchange with other willing parties
2. Production-based entitlement: one's capacity to produce goods using one's own resources or resources that one hires from willing parties
3. Own-labor entitlement: gained by the processing of resources through one's efforts
4. Inheritance/transfer entitlement: gained through having goods given to one by another who legitimately owns those goods

So, access to food depends on employment status, income, and eligibility to receive social services or financial assistance, which affect one's ability to purchase food from the market (Sen 1998; Maxwell and Frankenberger 1992). It is also a matter of land use rights, physical ability, and seed ownership. All of the previously listed factors are in turn influenced by one's socially, politically, and economically relevant characteristics such as age, health, sex/gender, race/ethnicity, and caste or class.

Access to food is most often discussed in scholarship and three topics: (1) food security, (2) food deserts, and (3) food justice.

Food Security

In his monograph titled *Poverty and Famines*, Sen (1998) argues that hunger and famine are not usually most directly the result of inadequate agricultural yields or food supply. Rather, hunger and famine are most immediately caused by economic, political, and social marginalization (Sen 1998). In other words, food insecurity is generally not, as many might assume, primarily determined by the availability of food – it is, instead, determined by access to food. If one considers historical cases, one finds that both increases and decreases in the rate of undernutrition are often relatively independent of food supply (Sen 1998). One example of this can be found in socialist countries such as China in the latter half of the twentieth century.

Sen (1998) notes that in countries such as China, rates of starvation have decreased (or been eliminated) with the inception of socialism even though there often has not been any substantial increase in agricultural productivity or food supply relative to the size of the population. Rather, the explanation for such reduction in under-nutrition is the result of changes in the entitlement system, specifically the strengthening of social security, guaranteed employment, and mandatory increases in wages (Sen 1998).

Moreover, famine and starvation can occur even without decreases in productivity, and even in instances when famine is the result of decreases in agricultural yields, hunger is never evenly distributed throughout the population (Sen 1998). When agricultural systems collapse and food supplies crash, those with adequate wealth and social status tend to avoid undernutrition (Sen 1998). Instead, it is those who are marginalized or are poor who tend to go hungry because they lack the ability or resources to weather disruptions to the food system (Sen 1998).

Sen (1998) cites several examples to illustrate the above cases: the Great Bengal Famine, the Ethiopian famine of the early 1970s, famine in the Sahel in the late 1960s, and the famine within Bangladesh in 1974 (Sen 1998).

Sen (1998) suggests that in all the above cases, hunger, starvation, and mortality rates far exceeded what one might expect given only the decreases in food supply. Instead, in these cases, the factors most likely to be responsible for famine include: trade disruption or commodity speculation leading to price increases, increases in rates of rural poverty, commodity speculation, decreases in the price of land and livestock (which led to loss of wealth), lack of insurance for fluctuations in the prices of cash crops, and inflation outstripping wage increases (Sen 1998). These factors all, in one way or another, resulted in increases in the price of food relative to average income. Because of this relative increase in food price, the most impoverished segments of the population lost the capacity to purchase the necessary amount of calories to maintain health. Thus, many went hungry despite there being

food that they could have eaten if they would have been able to afford it.

The examples of the Great Bengal Famine, the Ethiopian famine, famine in the Sahel, and the famine within Bangladesh – if Sen (1998) is correct – demonstrate the importance of food access for food security. The importance of access for food security can be found in the food deserts that have sprung up within inner cities and the rural countryside of the United States (Beaulac et al. 2009), Canada (Smoyer-Tomic et al. 2006), the United Kingdom (Wrigley 2002; Furey et al. 2001), and Australia (O'Dwyer and Coveney 2006).

Food Deserts

The term “food desert” was first coined in a report by the Nutrition Task Force Low Income Project Team of the UK Department of Health (Beaumont et al. 1995). There are a number of ways that food deserts have been defined, but one of the clearest and most concrete is offered by the US Department of Agriculture (USDA) (2015). The USDA (2015) considers a census tract to be food desert if it meets two criteria.

First, it must have a poverty rate of 20 % or higher, a median family income that is less than or equal to 80 % of the state, or be a tract within a metropolitan area and has a median family that is less than or equal to 80 % of the median family income of that metropolitan area. Second, it must have limited access to food. The USDA (2015) categorizes a census tract as having limited access to food if a substantial portion (where “substantial portion” is understood as instances where one of the following obtains: at least 100 households, at least 500 people, and at least 33 % of the population or where the ratio of households outside the minimum distance or with limited use of a vehicle relative to households within the minimum distance or has a vehicle available is 5–1.) of households within that tract must be further than 1 mile from a supermarket if the tract is urban or 10 miles if it is a rural. (However, the USDA (2015) in some instances instead employs a 0.5-mile minimum distance for urban tracts and a 20-mile

distance for rural tracts or considers household vehicle availability.)

In essence food deserts are areas where it is difficult to purchase fresh fruit, vegetables, and meat from vendors within reasonable walking distance. The residents in those areas, to obtain fresh food, must then have (1) reliable use of an adequately well-maintained car; (2) have access to public transportation, the physical ability to carry groceries for an extended period, and available free time to be able to regularly take lengthy trips to relatively faraway grocers; or (3) have the use of enough land, time, knowledge, and physical capacity to grow their own food. Moreover, the factors listed above in this paragraph all interact with income, social class, and health in a manner that tends to further disadvantage those who are already marginalized.

For example, in addition to having the least available funds for purchasing food, those with lower incomes are often the least likely to own their own car. As the USDA (2009) points out, car ownership is the most important predictor of whether a household has adequate access to food. Moreover, those with incomes below the poverty line are often the least able to have regular use of arable land and are the least able to grow their own food. Those with lower incomes are, for all the reasons above, particularly harmed by long travel distances to food.

The disproportionate impacts of the need to travel longer distances to access grocers become even more worrisome when one considers the areas most likely to have limited access to food. Areas of reduced food access have, in recent decades, proliferated throughout the inner cities and the rural countryside of the United States, the United Kingdom, Australia, and Canada (USDA 2015; Walker et al. 2010; O'Dwyer and Coveney 2006; Smoyer-Tomic et al. 2006; Wrigley 2002; Furey et al. 2001). This is noteworthy because poverty, in higher-income countries, tends to be concentrated within both inner cities and the country (Jargowski 2002; Alston 2000; Cloke et al. 1995; Tickameyer and Duncan 1990). According to the USDA (2009), at present a full 6 % of all households within the United States can be categorized as having limited access to food.

Within households considered lower income, the percentage with limited access can be as high as 38 % (USDA 2009).

Those with lower incomes, because they so often find themselves living within food deserts and lacking access to full-service grocers, find themselves reliant upon bodegas, fast-food restaurants, and liquor stores for food (Ornelas 2010). Their diets, as such, tend to include proportionally more processed foods that are more shelf stable and do not require refrigeration or specialized handling (Ornelas 2010). These processed foods tend to be more calorically dense and contain more refined sugars, fats, and sodium compared to fresh foods (Ornelas 2010), which contributes to higher rates of obesity and obesity-related disorders (such as cardiovascular disease and diabetes) within those living within food deserts (White 2007).

With the above being the case, food deserts have become a topic often discussed by those concerned with food justice.

Food Justice

Food justice was first defined by Lang and Heasman (2004) as involving the correction of “the maldistribution of food, poor access to a good diet, inequities in the labour process and unfair returns for key suppliers along the food chain.” This sentiment is echoed by Gottlieb and Joshi (2010) who assert that food justice is a matter of “ensuring that the benefits and risks of where, what, and how food is grown and produced, transported and distributed, and accessed and eaten are shared fairly.” Alkon and Agyeman (2011) expand upon Lang and Heasman’s and Gottlieb and Joshi’s definition, noting:

Essential to the food justice movement is an analysis that recognizes the food system itself as a racial project and problematizes the influence of race and class on production, distribution, and consumption of food. Communities of color and poor communities have time and time again been denied access to the means of food production, and, due to both price and store location, often cannot access the diet advocated by the food movement. Through food justice activism, low-income communities and communities of color seek to create local food systems that meet their own food needs.

Common to these definitions is the notion that just food systems are ones in which all segments of the population have equitable access to healthy food.

In addition to the food deserts discussed above, scholars concerned about food justice have identified a number of phenomena that contribute to the inequitable access to food in a manner that has resulted in harm to marginalized populations. One commonly cited example are the recent farm bills within the United States that have resulted in the global food system becoming increasingly integrated into a small number of agribusinesses (Gottlieb and Joshi 2010). Those concerned about the integration of the food system argue that such integration contributes to the homogenization of diets around the world, which leads to adverse health outcomes for a many of those living in lower- and middle-income countries (LMICs) (Popkin et al. 2012; Wilkinson 2004).

Gottlieb and Joshi (2010) suggest that the agricultural policy of the United States – manifested primarily through farm bills – has emphasized “export-oriented agriculture.” More specifically, it endorses and promotes the view that the agricultural sector within the United States should endeavor to produce surpluses of commodity crops that can then be traded to other countries.

However, Gottlieb and Joshi (2010) argue that adoption of agricultural policy that focuses primarily on the growing of surpluses for export has resulted in programs that tend to favor ever larger farms that can make the most of efficiencies of scale and use of Green Revolution technologies to maximize yields. This, in turn, has led to the consolidation of land and the elimination of small family farms (Gottlieb and Joshi 2010). The emphasis on the production of surpluses for export within agricultural policy has also led to the integration of the firms producing agricultural inputs and food processors into a small number of very large “agribusiness” conglomerates (Gottlieb and Joshi 2010).

The formation of these conglomerates has allowed for the existence of entities with the resources and wherewithal to capture the regulatory process through lobbying of congress and various federal regulatory bodies (Gottlieb and Joshi 2010). This

regulatory capture then reinforced the continuing promotion of federal legislation and regulatory actions that tended to favor large firms over smaller independent operations throughout the agricultural sector and the food system (Gottlieb and Joshi 2010). Indeed, partly due to the impact of this stacking the deck in favor of larger operators, by the 1990s somewhere between 70 % and 80 % of the market share for food within the United States was held by just five companies (Wilkinson 2009).

The concentration of market share into the control of such a small number of entities alone is sufficient to affect access. It limits the options available for the general public. With control of such a large a proportion of the available food being concentrated to five firms, it becomes quite difficult for the public to purchase products other than those offered by those firms.

With the above said, the emphasis on export within American farm bills has not only reshaped the food system within the United States; it has had effects throughout the world (Gottlieb and Joshi 2010). A clear example of this can be seen within the food systems of many LMICs. As of 2013, the United States exports over \$45 billion of processed food per year with a large portion of it going to LMICs such as Mexico, China, and the Philippines (USDA 2014). The trade of processed food from the United States and other high-income countries into LMICs has grown to the point that they now account for more than a third of all exports (Wilkinson 2009). These exports when combined with exports from the European Union and foreign direct investment on the part of agribusiness firms leading to the development of subsidiary companies within many LMICs have contributed to a substantial shift in global diets that is referred to as “the nutrition transition” (Popkin et al. 2012; Wilkinson 2009).

As the result of the influx of cheap imports from the United States and Europe, food prices in many LMICs have dropped to the degree such that native farmers are no longer able to compete and as such have been forced off the land (Stuckler et al. 2012; Stuckler and Siegel 2011). This has led to the rapid depopulation of rural areas within many LMICs and, more importantly,

the development of a “dietary dependency” to foods grown and processed by firms based in HICs (Stuckler et al. 2012). With the loss of local agriculture and food systems and the newly formed dependency on imports also comes the loss of access to many traditional foods.

As the result of this, as Khoury et al. (2014) have found, diets around the world have become increasingly homogenous. More specifically, in all of the countries they reviewed, they discovered that diets are converging on what they refer to as the “global standard composition” (Khoury et al. 2014). In the past most communities tended to consume diets based upon crops and livestock endemic to their region. That is no longer the case. Instead, at present, diets throughout the world tend to mirror those originally found in the United States and – to a lesser extent – Western Europe (Khoury et al. 2014).

The practical outcome of this is that diets, particularly those of communities living within LMICs, are including fewer fresh fruits and vegetables and now contain far more meat, refined sugar, fats, and oils (Popkin et al. 2012). As such, diets in many LMICs have also become far more calorically dense, and obesity rates within those countries have increased sharply in recent decades (Popkin et al. 2012).

Since the 1980s obesity rates have seen an annual increase of up to 5.7 % per year within some regions, and annual increases in obesity rates of 4 % are common throughout Latin America, Asia, and Africa (Popkin et al. 2012). Such increases in obesity come with a number of health risks. As noted earlier, being obese substantially increases one’s risk for disorders such as sleep apnea, diabetes, and cardiovascular disease – all of which are associated with higher rates of mortality (Kopelman 2000).

The strategies that have been proposed as a means to address the above-discussed problems also concentrate on the topic of food access, specifically how such access can be improved. For example, Gottlieb and Joshi (2010) refer to the efforts of La Via Campesina. La Via Campesina is an international network of smallholder farmers who advocate for land reform as a means of restoring regional food sovereignty and

independence. This is done in the belief that, given that much of the world’s most impoverished persons are farmers, providing small farmers with the opportunity to grow their own food will likely serve to reduce hunger by providing the currently food insecure with the capacity to control and have more direct access to their food (Holt-Gimenez 2011).

In general, strategies to improve equity within food systems involve shortening the distance between farmers and consumers as a means to improve the ability of consumers to influence the manner in which their food is grown and distributed (Loo 2014). Specifically, the literature concerned with food justice tends to endorse some combination of three approaches to ensuring food security for underserved communities and populations: (1) restoration of locally owned and operated markets where farmers can vend directly to their customers, (2) development of community-supported agriculture, and (3) alternative local agriculture such as community or urban gardens (Loo 2014; Alkon and Agyeman 2011; Gottlieb and Joshi 2010).

The advocates who propose these solutions do so because they believe that these solutions would provide alternative sources of food and allow consumers to have more direct control of their food system (Loo 2014). With more options and control of their own food systems, the currently food insecure could better insulate themselves from having their access to food denied by circumstance or the activity of others (Alkon and Agyeman 2011; Gottlieb and Joshi 2010).

Conclusion

Food access has come to be understood as primarily a matter of exchange entitlement. Whether one has enough to eat is often less dependent upon how much food is present than it is upon economic, social, and political factors affecting one’s purchasing power and ability to make use of land and other resources necessary for agriculture. This manifests in problems such as the food deserts that have been appearing in recent decades throughout the United States, the United

Kingdom, Canada, Australia, and other countries. Access to food has also entered into the literature concerned with food justice. In the food justice literature, loss of access to traditional diets has been blamed for increases in rates of obesity and associated adverse health outcomes. Improving access to food has also been proposed as a means to restore equity within food systems.

Access to Land and the Right to Food

Introduction

Examining the relationship between access to land and the right to food requires that we first define what we mean by access to land on the one

hand – thus, both land and access – and the right to food on the other. We will then briefly draw the complex relationship existing between access to land and the right to food. Finally, we will propose a short analysis of the issue against the current international backdrop of rising commercial pressures on land and then conclude.

Access to Land

Land is, in a first definition, “the part of the earth’s surface that is not covered by water” (*Oxford English Dictionary*). It is not simply “everything but water” but bears certain features that make it a particularly complex resource. Land does not move; it is heterogeneous and indispensable to almost all human activities; land is inherently linked to notions of identity and authority as well as territory, and it distinguishes itself by the power and depth of the sense of belonging people feel to it (Hall 2013). In this article, we will not consider the role of land as space and territory but solely as a resource, given our focus on food. The relationship between land and food will be examined below after a brief account of the right to food.

Access entails “the ability to benefit from things – including material objects, persons, institutions, and symbols” (Ribot and Peluso 2003, p. 154). Property is one of several possible (institutional) means toward achieving access. It is “a right in the sense of an enforceable claim to some use or benefit of something,” an enforceable claim being “one that is acknowledged and supported by society through law, custom, or convention” (Macpherson 1978, p. 3). Property refers only to claims that are sanctioned by socially legitimate politicolegal institutions – these institutions being effectively legitimized if their interpretation of social norms is heeded (Lund 2011; Sikor and Lund 2009).

We take the opposite of access to be exclusion, defined as “the ways in which people are prevented from benefiting from things” (Hall et al. 2011, p. 7). A good or resource is excludable insofar as it is feasible to exclude others from access to and use of the good or the resource (Ostrom 2003). While it has been convincingly argued that inclusion is intrinsic to property

(Dagan 2011), the ability to exclude is generally regarded as a defining feature of property rights (Rose 1994).

Right to Food

The right to food protects the right of all human beings to feed themselves in dignity, either by producing their food or by purchasing it. As authoritatively defined by the Committee on Economic, Social and Cultural Rights (CESCR) “The right to adequate food is realized when every man, woman and child, alone or in community with others, has physical and economic access at all times to adequate food or means for its procurement” (General Comment No. 12, para. 6).

The legal basis for the right to food in international law lies in Article 25 of the Universal Declaration of Human Rights, which recognizes the right of everyone “to a standard of living adequate for the health and well-being of himself and of his family, including food” (Universal Declaration of Human Rights, Art. 25). This right is also protected by the International Covenant on Economic, Social and Cultural Rights (ICESCR), which stipulates that states “recognize the right of everyone to an adequate standard of living for himself and his family, including adequate food, clothing and housing, and to the continuous improvement of living conditions” and requires them to “take appropriate steps to ensure the realization of this right” (ICESCR, Art. 11.1). Finally, the right to food is recognized in the Convention on the Rights of the Child in Articles 24.2(c) and 27.3, as well as in a number of other international and regional instruments. The CESCR provides an authoritative interpretation of the content of the right to food and guidelines for its progressive realization in the abovementioned General Comment No. 12, and the Voluntary Guidelines adopted in 2004 under the auspices of the FAO complement it with recommendations.

Three key elements form the core content of the right to food: availability, accessibility, and adequacy. First, availability requires that food should be available from natural resources and/or in markets and shops, which means that

there exist mechanisms to move food from the site of production to where it is needed in accordance with demand. Second, accessibility requires economic and physical access to food to be guaranteed, meaning that food must be affordable (without compromising any other basic needs, such as school fees, medicines, or rent) and accessible to all, including to the physically vulnerable, such as children, the sick, persons with disabilities, or the elderly, for whom direct access to food may be difficult. Third, adequacy means that the food must be safe and satisfy dietary needs, taking into account the individual’s age, living conditions, health, occupation, sex, etc.

The right to food, like other economic, social, and cultural rights, places three forms of domestic obligations on States. First, the obligation to respect existing access to adequate food requires State parties not to take any measures that result in preventing such access. Second, the obligation to protect requires measures by the State to ensure that companies or individuals do not deprive other individuals of their access to adequate food. Third, the obligation to fulfill (facilitate) means the State must proactively engage in activities intended to strengthen people’s access to and utilization of resources and means to ensure their livelihood, including food security. Whenever an individual or group is unable, for reasons beyond their control, to enjoy the right to adequate food by the means at their disposal, States have the obligation to fulfill (provide) that right directly.

The Food and Agriculture Organization of the United Nations developed the so-called PANTHER framework, deriving from human rights treaties a number of principles – namely, Participation, Accountability, Nondiscrimination, Transparency, Human dignity, Empowerment, and Rule of law (FAO 2009). States ought to follow these in order to create monitoring mechanisms, both judicial and nonjudicial, of decision-making processes to advance the right to food. Participation means that everyone should have the right to subscribe to decisions that affect them; accountability requires that elected representatives and government officials be held accountable for their actions through elections, judicial procedures, or other mechanisms; nondiscrimination

prohibits arbitrary differences of treatment in decision-making; transparency entails that people be able to know processes, decisions, and outcomes; human dignity requires that people be treated in a dignified way; empowerment requires that they are in a position to exert control over decisions affecting their lives; and rule of law, that every member of society, including decision-makers, must comply with the law (Cotula et al. 2008).

Access to Land and the Right to Food: Drawing the Relationship

The relationship between access to land and the right to food is not obvious, nor ubiquitous. In many cases, the right to food can entirely be fulfilled without access to land being provided through means such as formal employment with high-enough wages or off-farm business activities. However, for rural households in the global South, land is the strongest and oftentimes the only guarantee of relative food security (Cotula et al. 2008, esp. pp. 23 and 59). More generally, it is estimated that 80% of the billion people suffering from hunger today – mostly smallholders as well as agricultural workers, herders, artisanal fisherfolk, and members of indigenous communities – depend on land for their livelihood (De Schutter 2010). Among them, many farmers can only cultivate plots of land that are too small or not irrigated enough to ensure subsistence. In addition, peasants are usually poorly protected by law, which makes them vulnerable to various limitations on their activities including, in extreme cases, evictions.

Insofar as land rights ensure access to productive resources and are key for realizing the right to food – that is, when there exists no alternative means of producing or purchasing food that is sufficient, adequate, and culturally acceptable – they are of paramount importance. But land ownership and use are often subject to confused and intertwined regulation, combining, for example, customary law (i.e., administered in accordance with the customs of indigenous groups) and statutory tenure (usually introduced during colonial

periods) – not to mention the array of laws and codes at the international scale.

In addition, realizing access to land is extremely complex. First, one needs to distinguish property rights and effective access since rural households can have either one without the other (Hall 2013). Property alone does not ensure that rural households will be able to derive benefit from the land (to “access” it) but needs to be complemented with “structural and relational mechanisms of access” such as technology, capital, and markets (Ribot and Peluso 2003, p. 160). By contrast, people can have access to land (“benefit from it”) without property rights – through agricultural labor, for example.

Second, having in mind the focus on land as a resource, exclusion (i.e., nonaccess) from a specific piece of land (as opposed to any land at all) is essential to virtually every productive use of land by anyone (Hall et al. 2011, p. 4). Aspirations for land access necessarily include the wish for some degree of exclusionary power (Hall et al. 2011, p. 7). This key dilemma causes manifold tensions, which are particularly complex when it comes to the recognition and implementation of a positive right to land for land-dependent rural households (as distinct from a negative right not to be evicted from land already held) through land reforms or similar programs of land redistribution (Hall 2013). Thus, exclusion is inevitable and goes hand in hand with access, engendering dynamics that involve a wide range of actors, powers, and legitimizing narratives.

Beyond local and national tensions affecting access to land, the issue takes on new dimensions within the current wave of international land transactions, which can also be analyzed according to the benchmark of the right to food. The land, water, and other resources that have supported local groups’ livelihoods for generations are now increasingly being subtracted from their access and control and converted into large-scale agro-industrial plantations, aimed to a considerable extent at nonfood production (see the data available at <http://www.landmatrix.org/>). This transformation from small-scale farming for personal and/or local production to large agrobusinesses can threaten food security

inasmuch as agricultural products are generally sent abroad, bypassing domestic markets. Moreover, the deals provide few or no guarantees for small landholders and are therefore likely to negatively impact the most vulnerable groups. Besides, although small-scale farmers sometimes resort to techniques that are detrimental to the environment, these large monocultures with intensive use of pesticides and mineral fertilizers aggravate in a much more powerful fashion soil erosion, groundwater contamination, and climate change, through the significant amount of greenhouse gases they entail. In the mid- to long run, this is expected to considerably diminish both the quality and the availability of natural productive resources, hence to reduce the ability of rural communities to feed themselves. Thus these large-scale land leases and acquisitions are likely to pose considerable challenges to the realization of the right to food by bringing about changes regarding access to land, choice of products to be cultivated, and where these products are sold (i.e., international or domestic markets) (Cotula et al. 2009).

Conclusion

The access to land of rural farming households in the global South is jeopardized by a variety of dynamics, spanning from local to international dimensions. It is an extremely complex issue especially in its positive side (to be granted access), but it is also under fire in its negative component (not to be deprived from current access) due to growing commercial pressures on land worldwide.

In this context, to borrow Amartya Sen's formulation, "the law stands between food availability and food entitlement" (Sen 1981, p. 166). This statement highlights the central role of legal entitlements in ensuring that the most vulnerable have access to the necessary resources to either produce enough food or have a purchasing power sufficient to acquire food in the market. Since hunger does not result so much from a lack of food production as from institutional bottlenecks and deficient economic and political empowerment

(Cruz 2010), the place of human rights in the design of strategies and mechanisms to combat hunger becomes fully meaningful.

In particular, public policies aimed at improving access to food, and to land when it appears as a necessary means to this end, should target the most marginalized, enable and foster participation, enhance accountability and monitoring, and engage in individual and community empowerment. These touchstones are no silver bullet, yet they are conditions to improve entitlement to land and ultimately to food as a resource indispensable to life.

Summary

The right to food does not necessarily translate into a right to land. Yet, for most of the world's hungry, access to land is a condition to guarantee their livelihood and to achieve a decent standard of living. Thus, the relationship between these notions is far from simple. Moreover, given the various layers of significance attached to land as well as its many dimensions, realizing access to it is fraught with complexities as well. Nonetheless, the issue has to be explored, even more so in the current context of rising commercial pressures on land worldwide and the far-reaching transformations they entail.

Introduction

Can a meal be a work of art? Do eating and drinking afford experiences that qualify as “aesthetic”? If so, how do the artistic or aesthetic aspects of foods relate to ethical issues? While moral questions about eating have been under philosophical discussion for a long time, its place in aesthetics is more recent, and the relationship between ethical and aesthetic value is as contentious with food as it is with art.

Eating is both a biological necessity and a cultural practice. Every living creature must nourish itself; however, necessary sustenance often comes at the expense of the life of some other living thing. This fact alone opens ethical questions if one considers eating another sentient creature a practice with moral standing. What is more, habits of eating reflect upon character – for eating can be greedy or abstemious, convivial or solitary, enthusiastic or inattentive. Questions about the tastiest things to eat merge with ethical questions about what is appropriate to eat and whether there are potential foods that should be off-limits, for cultural and religious traditions forbid eating just anything that might nourish a human body.

Quite apart from nourishment, eating can afford intense and immediate enjoyment. Food

appeals to the senses – most immediately to the senses of taste and smell but also to vision, touch, and even hearing. With the development of different cuisines, one also finds norms of presentation and standards for quality of preparation. Such factors suggest that foods also possess aesthetic value, though this claim requires some defense given traditional concepts of the aesthetic, which usually exclude physical satisfaction. Similarly, the status of food as an art form is more complicated than at first it might appear, for some of the most influential philosophical traditions that have produced aesthetic theories and philosophies of art have not welcomed cuisines into their purview. The reasons for this rejection are closely related to the ethical values that are accorded to food, the body, and the necessity of eating.

Recent philosophy has become more receptive than in the past about acknowledging the aesthetic significance of the literal sense of taste and of its objects: food and drink (Kaplan 2012). This change of perspective needs to be understood against the backdrop of centuries of assumptions about the nature of beauty, art, and the human body. Preliminary historical orientation is needed to place the issues in context – or contexts in the plural, for these topics have been treated variously over time by philosophers of different theoretical orientations. The history that follows chiefly concerns the traditions of Europe and the so-called Western philosophies that trace their origins to classical Greece. This discussion prepares the way for some recent approaches to the aesthetics of food and drink and the ethical complexities that they disclose. Comparison with other philosophical traditions would reveal additional contexts that bestow meanings and values on food and eating.

Food and the Body: Some Enduring Concerns

In the works of two of the founding philosophers of the West, one finds conflicting attitudes toward food and eating, attitudes that represent recurring perspectives on the body and its frailties. In his influential dialogues, Plato takes a notoriously hard line on anything that indulges the body and

leads the mind to dwell on its physical vehicle rather than on abstract thinking. His particular type of dualism values timeless spiritual and intellectual existence over physical natures of any sort. Human bodies and the material world in general are temporary and unstable; devoting attention to them poses epistemic dangers, inhibiting the ability to grasp the nature of timeless Truth, and moral dangers – for it deflects the attempt to learn of the Good. This is especially evident with the temptation to pursue bodily pleasures, which the senses of touch and taste present with special force. As Socrates famously pronounced on his deathbed, a philosopher should be concerned with neither food and drink nor sex.

Plato's younger contemporary, Aristotle, takes a more moderate approach to eating and its enjoyment. His attitudes about food are also integrated into his ethical theory, which recommends that one seek a mean between extremes when learning to exercise both the emotions and the senses. One of the central virtues of Greek ethics is moderation or temperance, the characteristic that pertains to the way we handle pleasures. Aristotle is no ascetic, and he regards taking pleasure in bodily activities such as eating to be part of a good life. It is the extremes of eating that a virtuous person must avoid: neither deprivation to the point of malnourishment nor overindulgence to the point of gluttony represents virtue.

Plato's general attitude to the body can be found in many other traditions as well. This sort of approach worries that sensuous pleasures can capture attention so powerfully that they lead to both thoughts and actions that violate the prescriptions formed by rational deliberation. Employing the sense of taste for the pleasures it affords might exercise the body at the expense of the soul, and overindulgence in eating and drinking has consequences for health as well as morals. If the food is especially tasty, so much the worse, for the temptation is all the stronger.

Similar sets of values can be discerned in the many religious traditions that prescribe fasting. Depriving the body of sensory satisfaction is a time-honored means to feed the spirit and direct attention away from quotidian needs. Fasting can take on a variety of meanings, from

acknowledging the frailty of the body and its physical demands to prompting thoughts of the importance of fleeting pleasures, all the sweeter when restored and the fast is broken. The many and varied practices of fasting indicate how the values ascribed to eating always entail perspectives on our bodily nature. The idea that overindulgence in sensuous pleasure does not represent a good life is captured not only in Aristotle's doctrine of moderation but also in the cardinal sin of gluttony in traditional Christianity, in ancient sumptuary laws that forestall excessive displays of wealth that may be evident in lavish tables, and in contemporary controversies over the causes and meanings of obesity and eating disorders. Thus far, recognition of ethical considerations attached to food and drink concerns the eater: how to promote health and prevent misuse of bodies and minds. Attention is directed to the human being and his or her sustenance rather than to the moral standing of creatures treated as foods, a topic to be addressed shortly.

The putative ethical and epistemic shortcomings of tasting and eating lay the foundation for parallel shortcomings of an aesthetic nature. While there are more or less attractive ways to present food, terms such as "beautiful" are usually reserved for objects that we see or hear, whether in encounters with nature or with art (Sweeney 2007). Because eating satisfies bodily needs, its pleasures are also bodily. What later generations recognized as a distinction between the "aesthetic senses" of vision and hearing and the "non-aesthetic senses" of taste, touch, and smell is already present in venerable worries about bodily pleasures. The aesthetic-nonaesthetic distinction receives fuller treatment in the philosophies of taste that emerged in European Enlightenment philosophy.

Aesthetics and Theories of Taste

The term "taste" is used as a foundational metaphor in modern aesthetic theory, for the gustatory sense provides a model for understanding the ability to discern the subtle qualities of objects. The metaphor is founded on several

characteristics of literal taste, including the fact that it is only by actually sampling a dish that one can determine its quality – e.g., if the seasonings are in balance or the cooking complete. This sort of firsthand acquaintance also obtains with the good judge of art who determines if a work is beautiful. Gustatory taste, like aesthetic sensibility, is also educable, requiring experience and education in order to become fully discerning. For these reasons, taste represents a facility for making aesthetic judgments that indicate expertise or connoisseurship.

(The sense of taste plays a robust aesthetic role in at least one other philosophical tradition as well, the classical Indian theory of *rasa*, which describes a complex range of sensory and emotional responses to different qualities in art. The two philosophical contexts are quite different, but both note the immediacy and intimacy of aesthetic response when one tastes flavors and is moved by the experience of a work of art.)

With taste playing such a central conceptual role in modern aesthetic theories, one might expect that food would have been accorded aesthetic value readily and automatically. However, this was not the case, for taste and smell – the coordinating gustatory senses – present difficulties that hamper the formulation of an important philosophical objective. In particular, they make it difficult to figure out a “standard” of taste, a necessary normative goal if one wants to avoid a free-for-all regarding the merits of art and aesthetic judgments. Taste and smell were – and often still are – considered highly “subjective” senses. The senses of sight and hearing provide information about the world around that grounds the development of knowledge, and touch acts as an anchor to assure a perceiver that he or she experiences material reality rather than illusion. But taste and smell appear to furnish little information about anything other than individual responses to substances. By severing aesthetic pleasure from the satisfactions of the body, theorists strove to escape the damaging subjectivism that supposedly prevents literal taste from achieving standards. The putative subjectivity of taste dogs the heels of aesthetics, and in debates about how to locate a standard of taste for judgments about art, contrasts are regularly

made to food. About taste there is no disputing, according to the old adage, so it does not matter if tastes for food and drink differ. But genuinely *aesthetic* taste requires some kind of normative standards, for clearly some art is better than others. Thus food enters the philosophical discourse of this time as a point of contrast. The aesthetic senses were identified as vision and hearing, and the old distinction between bodily and intellectual senses was reinforced in the burgeoning literature of early modern aesthetics (Sweeney 2012; Korsmeyer 1999, Ch. 2).

Cuisine: Art, Aesthetic Value, and Ethics

The rise of modern gastronomy in Europe fostered a body of literature that was attentive to the development of philosophies of taste and that sought to elevate gustatory pleasures into aesthetic regions and food and drink into the arts. Writers such as Jean Anthelme Brillat-Savarin and Grimod de La Reynière wrote about the pleasures of the table, the development of discerning taste for food and drink, and the importance of fine preparation of meals (Gigante 2005). These authors promoted the idea that elegantly prepared foods, far from merely assuaging hunger, are gustatory entries into the world of fine art (Sweeney 2012).

The emphasis of the gastronomical writers was invariably on the fine dining of a relatively elite class of people. They focused on the special feasts of those with sufficient leisure to spend time savoring a lengthy sequence of foods. This sort of meal preparation seemed to offer the best candidates for food as an art form, an assumption that is continued in the contemporary notion that it is fine, gourmet food that especially demonstrates aesthetic accomplishment and artistic merit. Such an approach is reasonable in order to separate well-prepared meals from junk food and dining from gobbling. But it comes with a price: the zone of attention for aesthetic merit is purely the enjoyment of the taste experience. That is, the aesthetic dimension of food is more or less limited to sensory pleasure. The comparison with fine art is accomplished because of the parallels between the discerning perception that is demanded by

both art and food, but the profound meanings that art can achieve are omitted from consideration. Literature, painting, and music are all art forms that convey expressive meanings, whether propositional or affective. They are also forms that are appreciated by means of the senses of vision and hearing, along with the imagination. Whether the sense of taste is capable of discerning meaning of similar breadth and complexity is a matter of debate and will be addressed again shortly. But it is widely believed that food, however tasty, does not convey or express meanings with propositional content (Telfer 1996).

Emphasizing immediate taste experience and the pleasures it affords also retains a fairly strong distinction between aesthetic quality (flavor and taste pleasure) and ethical implications (judgments about what is eaten, how it is prepared and consumed). As a result, moral meaning remains separable from aesthetic assessment. However, a closer look at the links between sensation and cognition will narrow the distance between the aesthetics and the ethics of eating.

Uniting Aesthetics and Ethics

The concept of the aesthetic has undergone many revisions in the last decades, as has the concept of art, both in philosophy and in the art world itself. Generally speaking, the parameters that were formulated to distinguish aesthetic from other values have become more porous than previously. In addition, as more is discovered about the science of the sense of taste, its hoary reputation as “merely subjective” has been revisited and revised. A reassessment of taste is required before the relationships among aesthetic qualities of foods, the knowledge they presume, and the ethics of eating can be fully considered.

So long as the sense of taste is believed to refer only to personal responses, it has little traction to command philosophical interest. And the idea that taste is merely relative is ancient and tenacious. The fact is, however, taste is a frequent topic of dispute, and increasing scientific understanding of the machinery of sensation supports the idea that there are many common foundations for taste

experiences, no matter how diverse preferences can become. Indeed, taste has a double direction, as it were, for it can refer to the properties of objects (and as such be “objective”) as well as to subjects (whose experience is “subjective”) (Smith 2007; Shaffer 2007). Gustatory taste thus admits of normative standards – as cooks and winemakers throughout the ages have understood. Unless one retains a restriction on bodily pleasures such that they never qualify as aesthetic in principle, taste rather easily joins the other senses with an aesthetic function. Are these seasonings balanced to perfection? Does this bottle of wine need another year before it is drunk? These are questions that are quite like those raised about whether a film, a piece of music, or a painting is satisfactory in its completion.

Does this mean that food should be included among forms of art? Some distinctions are required even to address this question. In recent decades some artists have begun to use food substances in their gallery works. Sometimes these works are meant to be eaten, other times they serve as a critique of and departure from traditional artistic media (Smith 2013). However, the question that is germane here does not refer to foods within the established institutions of the art world, but food that appears on the tables of homes and restaurants. Are these sorts of meals – at least those that are prepared with care – well understood as art? In a relatively loose sense, the answer can be “yes,” especially if we think of decorative presentations of carefully concocted dishes. There is little to preclude food from the category of the practical or applied arts (Telfer 1996). The similarity between food and fine art can be pursued by noting certain parallels with performance arts, since both are appreciated over a period of time in which they alter and disappear (Monroe 2007).

The degree to which the category of fine art suits foods and their preparation is a more complicated matter, however. The fine arts, a category arguably arising in the early modern period (Shiner 2000), are also the arts for which aesthetic value is considered paramount (as opposed to functional, moral, or religious uses, for arts are produced in all these venues). The appreciation of

fine art is analyzed as a kind of aesthetic pleasure. But as already noted, if sensuous taste pleasure is food's sole aesthetic measure, then connoisseurship is more or less the only parallel with the appreciation of art forms such as music and poetry. To go further requires a much stronger case qualifying food and drink as the bearers of the sorts of expressive meaning for which the arts are additionally valued.

In fact, the denial of propositional and expressive meaning to the experience of food and drink is disputable. As anthropologists and sociologists have long observed, social practices of eating bestow meaning on foods, and in the act of eating, we understand both what is being eaten and the importance of the contexts of meals. Once one notices the significant roles of eating not only in daily life but also in civic and religious ceremonies, the meanings of food are evident. (For examples, see Fletcher 2004.) Recognizing that food has not only aesthetic value in a narrow sense but also cognitive significance establishes that the aesthetic dimensions of foods are not limited to the enjoyments of a connoisseur (Korsmeyer 1999; Heldke 2011). Acknowledging the cognitive significance of food is important independent of the question of whether food ought to be considered an art form.

However, even if one grants that foods can take on meanings in their contexts of serving and consumption, a counterposition can be advanced with the observation that it is only those *contexts* that impart meaning, not the food itself. The source of understanding remains *external* to the eating experience because information that is independent of the act of eating is required to supply cognitive content, as the tastes of food alone will not do the job. If this were the case, then the aesthetic dimension of taste would still remain separable from its moral valence. That is, the aesthetic quality could be excellent (yum!) but the moral quality negative (too bad!). A final set of considerations unifies aesthetic and ethical values in eating, making this separation difficult to maintain.

Some would argue that knowledge about what we ingest does not affect taste experience (Bach 2007). But can this be true? Many tastes are

ambiguous without context, and identifying them brings the flavor into focus (Korsmeyer 2011). Unless we know we are eating blue cheese, for instance, its flavor may present as rotten. Sometimes detection of the identity of what is in our mouths entirely changes the valence of the experience, as when one discovers that one has eaten something considered taboo. Retrospective nausea can ensue from this disclosure, and what had seemed a pleasant taste now appears revolting. Separating aesthetic from ethical value in eating would require that there be two distinguishable mental events here: a good taste experience and a judgment that what tastes good is bad to eat. However, recall that "taste" has two directions of reference: the sensation and the substance. Knowledge of the substance is not irrelevant to the presentation of the sensation.

A large zone of ethical value opens when one acknowledges that knowing what one is eating, including how it was cultivated and prepared, can affect one's taste experience. One such context occurs with the now-popular practice of food adventurism, such as cooking dishes from unfamiliar traditions, patronizing restaurants opened by immigrants to one's community, or traveling to sample "exotic" cuisines. These tasting experiences may be respectful and admiring, but if one considers the circumstances that have placed, say, an Ethiopian restaurant in downtown Los Angeles, the possibility of such eating leads one to consider wars, famines, and population displacements (Heldke 2003).

It must be granted that sometimes the foods we eat have ethical valence that must be discovered by means that are indeed external to its aesthetic presentation. Whether a tuna fish sandwich can be linked to the incidental drowning of dolphins in long tuna nets, for example, would not be manifest in the taste of lunch. However, at other times the very suffering of a sentient being is required for a certain taste to be present. Jeremy Strong identifies a category of "cruel food," in which the very taste of the food depends upon a mode of preparation that causes suffering (Strong 2011). Overstuffing a goose for foie gras and depriving a calf of nutrients to impart a pale color to its meat are two familiar examples of cruel food. In cases

such as these, moral valence is present in flavor itself, and ethical and aesthetic properties are inseparable (Korsmeyer 2012). The gourmet intent only on the flavor produced might try to detach the aesthetic and the ethical values of cruel foods, such that aesthetic value remains positive while a moral squeamishness intrudes. But the permeability of cognition and sensation renders this separation at least disputable and possibly untenable.

Recent technology has brought a new eating possibility into the moral arena: artificially grown meats that were never part of the body of sentient beings (Wellin et al. 2012). This scientific innovation holds out the possibility of re-separating aesthetic from moral values. If laboratory scientists were able to produce flavors that previously were properties of cruel foods, would the tastes of such flavors escape moral worries? Perhaps, for example, one could retain the silken smoothness of foie gras without compromising the comforts of goose or duck. This solution is not without problems, however, considering the fact that tastes are always tastes of something or other. That is, there is always a cognitive dimension to flavor inasmuch as one at least recognizes or presumes the identity of what is tasted. If laboratory-grown meats are enjoyable insofar as they mimic the original source and fool the palate, then the character problem of eating cruel foods has not disappeared. The eater is happily deceived but is still enjoying a substance with a flavor that connotes cruelty. In the far more distant future, it is possible that food production will have developed to the point where eaters taste only essence-of-laboratory. But that possibility veers into the speculative realm of thought experiment, where one can only guess at what future moral intuitions might be.

Summary

Historically, philosophical theories often separate aesthetic and ethical value into different zones of experience. With food and eating, this separation would divide flavor and enjoyment from moral approval or disapproval of what is eaten.

However, taste experience is rarely wholly detachable from concepts of the substance that produces flavor, so ethical valence can be discovered in taste itself, uniting aesthetic and ethical qualities in eating experiences.

Globally speaking, 216 million fewer people today than in 1990 are suffering from hunger (FAO 2015, 8). At the 1996 World Food Summit in Rome, world leaders pledged to reduce the number of hungry people in developing countries from a billion in 1990 to 515 million by 2015. Though this target was missed by 260 million, the population increase of 1.9 million meant that almost two billion people had been freed from hunger (FAO 2015, 9). The global South continues by far to carry most of this hunger burden. Of the world's 795 million hungry today, 780 million (over 98%) are in the global South (FAO 2015, 8–9). 220 million (27%) are in sub-Saharan Africa (FAO 2015, 10), where a massive crisis in food security is well underway.

Research into African agricultural and food ethics focuses largely on commercial agriculture, concerning mainly genetically modified (GM) crops (e.g., MacDonald 2006; Powers 2006), but also animal rights and welfare, HIV/AIDS, land reform, biodiversity, medicinal plants, and agricultural science (e.g., van Niekerk 2010). This entry complements this work by prioritizing subsistence agriculture – the most common type of farming in Africa that affects the most people – in order to document Africa's rapidly growing humanitarian food crisis.

Issues including labor, food security, and nutrition are assessed in terms of environmental,

gender, climate, and intergenerational justice as appropriate, with attention to distributive justice throughout, and culminating in assessment of postcolonial, neoliberal policies in global economics. First, however, overview of African agriculture is provided. South Africa and North African countries have established industrial economies; discussion of Africa herein means sub-Saharan African countries where families rely on agriculture for food security.

Sub-Saharan African Agriculture

Of the estimated 570 million farms worldwide, approximately 9% are in Africa; of these, over 41 million are family owned, small holdings less than 2 hectares (5 acres) in size (Lowder et al. 2016, 25) that together produce 80% of Africa's food (FAO 2017, xi). Africa is fertile: in 2014, 42.1% of land in Africa was arable, compared to 37.5% for the planet as a whole (World Bank Group 2017). Commercial crops include coffee, cotton, cocoa, palm oil, sugar, tea, and tobacco, while subsistence farmers produce sorghum, millet, rice, cassava, yams, and sweet potatoes as staples (Mbabazi et al. 2015, 1) but also groundnuts, beans, and pecans and vegetables like tomatoes, peppers, and eggplant, as well as melons (Glazebrook 2011). Many smallholders keep animals, e.g., goats, cows, pigs, and guinea fowl, that provide eggs, milk, and dung for fertilizer or fuel for cooking fires, but are rarely eaten.

Subsistence farming is a livelihood strategy in which the main output is consumed directly. The farm is the family's principal source of income and typically involves some small-scale selling in local markets, often to buy schoolbooks or uniforms, cloth for making clothes, or pharmaceuticals. Agriculture is part of everyday life for many Africans. Half of the world's countries with greater than 80% rural dwelling are in Africa; Burundi is highest with 89% rural population. Agriculture supports livelihoods of 80% of Africans, though employing only 50% of the workforce and generating only 15% of the continent's GDP (Mbabazi et al. 2015, 1). Subsistence

agriculture does not figure in GDP and GNP that measure marketed crops.

Ethical issues in African agriculture and food pertain to either commercial or subsistence agriculture, to both, or in some cases to the tension between the two, e.g., when weak land tenure rights leave subsistence farmers vulnerable to land grabbing by commercial development projects. Practices addressed in contemporary food ethics in the global North, e.g., meat intake, locavorism, slow food, and organic farming, are not active choices but necessities arising from field-to-table, production-preparation-consumption patterns in subsistence economies where meat and distance-grown or purchased, prepared foods are scarce. African issues in food and agricultural ethics are different from those in the global North.

Food Security

The most pressing ethical issue is growing incapacity in Africa to maintain food security. In 2008, 21 of the world's 36 food-insecure countries were in Africa (Kabasa and Sage 2009, 21). This global disproportion has been steadily increasing: the proportion of the world's undernourished in Africa was 17% in 1990, but 27% by 2015 (FAO 2015, 10). In real numbers, undernourished Africans climbed from 169 million in 1992 to 212 million by 2005 (Kola-Olusanya 2012, 29). From 1990 to 2010, the number of African countries in food crisis doubled from 12 to 24, with 19 of them experiencing food crisis in 8 or more of the 10 years between 2005 and 2015 (FAO 2015, 27). Today, every fourth African is undernourished (FAO 2015, 12); 220 million Africans, many of them are children, do not have enough to eat (FAO 2015, 8). The 2017 African population of 1.2 billion is anticipated to reach almost 4.5 billion by the end of the century (UN 2017, 1). African food insecurity is accordingly doubly threatened by both population increase and decrease in agricultural yield.

Even without starvation, nutritional deficiency is a threat. In northern Ghana's Sudan savannah ecosystem, for example, women farmers are moving to rice rather than traditional crops of millet

and groundnut as an adaptation to unpredictable rains. The latter are high in protein, and millet is also rich in calcium important for growing children and pregnant or lactating women; rice however contains primarily carbohydrates. The nutritional base is accordingly being sacrificed in a desperate measure simply to have something to eat. The Sudan savannah ecosystem stretches from Africa's west coast to East Africa's Ethiopian Highlands, so the Ghanaian experience is likely shared across the continent. It indicates gender injustice as women are disproportionately affected and intergenerational injustice as health impacts of childhood malnutrition have lifelong consequences.

Increasing food insecurity is in part due to land degradation: by 1992, Africa had the largest proportion of degraded land of any continent (Scherr and Yadav 2001, 134). More important, however, are economic factors, e.g., supply bottlenecks, distribution complications, limited imports, as well as population displacement and extreme poverty (FAO 2008). Poverty and food production are deeply entangled. Poverty exacerbates food insecurity by affecting Africans' ability to remediate environmental damage, to purchase food when yields are inadequate, and to increase productivity by buying fertilizer and other extension services. At the same time, the World Bank suggests that 1% increase in crop yield in Africa could reduce the number of people living on less than \$1 USD per day by 0.72%, i.e., 1.5 million people (Aweto 2012, 187). In 2012, over 500 million Africans lived on less than \$2 USD per day (WHES 2016). The ratio of GDP growth against the number of farmers is lowest in the global South – gaps are expanding between food needs and crop yield. Mineral wealth, e.g., discovery of oil, can “crowd out” the agricultural sector (Sachs and Warner 1995); oil is exported for use mostly in the global North, with climate impacts on African agriculture detailed below.

Labor

For laborers, commercial production uses fertilizers and pesticides that generate health impacts,

while mechanized equipment can risk safety. Weak or nonexistent minimum wage standards and government regulation of farmworker rights and corruption make labor easily exploitable, including sexually. Displaced farmers face worse conditions selling their labor than growing for themselves. In large-scale plantations, child labor reproduces slavery conditions, with minimal nutrition, education, healthcare, and protection from abuse. In Ghana and Ivory Coast, two million children perform unpaid hard labor in hazardous conditions in the cocoa industry (Fair Trade USA 2017).

Subsistence farming uses family labor. Food production is grounded in relations within and between households that affect decisions about crop selection, when to plant and harvest, as well as knowledge management and marketing. Keeping children out of school to help with farming affects literacy and graduation rates. Taking daughters out of school in regions where women traditionally farm exacerbates gender inequities, but is hard to counter since families depend on crops for food security and some income. On rare occasions, nongovernment organizations provide funding to hire labor in the daughter's place.

Gender

Women in agriculture make up 70% of the world's farmers (Women for Women International 2010) and produce most of Africa's food. In Ghana, for example, they fill 87% of the national food basket (Social Coalition Watch 2010). Failure of traditional economics to recognize subsistence farming thus excludes women's livelihood in development, agricultural, and economic policy. Even more recent Genuine Progress Indicators fail to account for women's crucial contribution to food security that supports African economies (Glazebrook 2011). So women continue to face limited access to credit, machinery, labor, fertilizer, and agricultural extension services. Weak land tenure rights render women vulnerable to large-scale land acquisitions blocking local access and known to cause declines in production (Cotula et al. 2009). Agricultural ethics thus

intersect with gender ethics in the form of distributive justice failures in workload parity and resource allocation, and recognition justice failures concerning women's role as food providers and economic agents.

Environmental Justice

Environmental injustice is rampant in Africa's agricultural sector where most farmers have few resources, political and social tools, or empowerment to respond. Land grabbing enables large-scale, mechanized, capital-intensive, monoculture production of food or biofuel crops for export, but increases lived poverty by displacing locals, depleting local water resources, and contaminating the area with chemical fertilizers and pesticides or GM organisms that outcompete traditional crops. When development projects fail, appropriated land can lie empty yet frustratingly inaccessible for locals who used to farm it.

Pollution brings health issues. Resource extraction industries, i.e., mining and oil, poison land and water by dumping tailings and leaving spills unchecked. In Nigeria, for example, this caused 60 years of resistance culminating in the hanging of the Ogoni 9 for their leadership in protesting Shell's activities in the Niger Delta. The Ogoni Women activist group subsequently blocked attempts to drill on Ogoni land for 10 years, causing Shell's lease to expire because of inactivity (Glazebrook and Kola-Olusanya 2011). Yet Shell was not required to compensate livelihood losses or remediate contaminated land and water – locals remained obliged to give their family contaminated food and water. Distributive justice was doubly breached as those who paid the health and livelihood costs of Nigeria's oil development were denied the benefits of this multi-billion dollar industry.

Control of water also generates environmental injustice. In 2007, when floods wrought havoc in Burkina Faso, dams were opened to relieve local impacts. The ensuing swell exacerbated flooding in downstream neighbor Ghana. Dozens died, over 300 thousand were displaced, and many lost their entire annual crop (Glazebrook 2011).

The majority of farmers impacted were women supporting extended families separated by urban migration and already devastated by AIDS; the most vulnerable with least resources were most strongly affected.

Elsewhere, trans-boundary water issues drive war, conflict, and confrontation, e.g., between Egypt and Ethiopia, as upstream dam development reduces flow across borders downstream. Subsistence farmers who depend solely on rains experience less impact from trans-boundary water control than corporate farmers whose water use in agriculture includes irrigation, though their lives may be affected in other ways, e.g., water availability for daily family needs.

Climate Justice

The factor most impacting African agriculture is global climate change that intersects with the issues detailed above and is predicted to exacerbate and accelerate existing agricultural challenges. In 2007, the Intergovernmental Panel on Climate Change (IPCC) projected that by 2020, 75 million to 250 million people in Africa would be exposed to increased water stress due to climate change, and that decreased yields from rain-fed agriculture could severely compromise agricultural production and food access (IPCC 2007, 50). By 2080, production is expected to experience catastrophic declines in grain number, size, and quality of 20–30%, with declines as high as 50% in Sudan and Senegal (Cline 2007). By the twenty-first century, only 3.7% of arable land in Africa was irrigated, while fertilizer consumption was the lowest globally, averaging 9 kg per hectare against the average of 109 in the global North and totaling only 1% of global usage (NEPAD 2002). Many farmers fertilize only through collection of animal dung (Glazebrook 2011), and 60% of Africans depend for survival on livestock to provide this dung, as well as occasional protein in the diet and other resources for various uses. Climate change impacts will mean less forage and feed crops, and less water for animals. Subsistence agriculturalists simply cannot usually afford agricultural extension services like fertilizers or

expensive inputs like GM seeds. South Africa produces only 1% of the world's GM crops, and the rest of Africa combined produces well under 1% (UN 2008, 21). African agricultural communities thus suffer severe damage from climate change.

Changes in rainfall patterns have already been making it harder for farmers to know when best to sow, cultivate, and harvest (Jennings and Magrath 2009). Decreased yield has been correlated to the global temperature increase. Rice, for example, undergoes 10% decline for each 1 °C rise (Peng et al. 2004). The IPCC's 5th Assessment Report (AR5) notes the special vulnerability of marginalized groups to climate change that exacerbates other livelihood stressors, e.g., decreasing crop yield, for people living in poverty (IPCC 2014, 6–8). AR5 projects with high confidence that a global mean surface temperature increases by 2 °C will put African crop productivity near *medium risk* by 2030 and well into it by 2080, even with adaptation. Models show *very high risk* to African agriculture for a 4 °C rise (IPCC 2014, 21).

Women and children are extremely vulnerable to incremental climate impacts on food and agriculture, though they have the least political, economic, and social resources to recover (Peacock et al. 1997; Morrow 1999; Bang 2008). Politically and economically marginalized women lack access to government or other aid through loans and grants. They often cannot relocate when growing conditions deteriorate as they do not have the resources to move and may be constrained by other barriers, e.g., language. They are the primary medical caregivers in many families, so water-vector, insect-carried sicknesses like malaria, anticipated to be more common with climate change, increase their workload in the home and in the field when sick family members cannot contribute their labor, as well as threatening the woman's health. Children facing climate-induced food insecurity can suffer nutritional deficiencies that have developmental and lifelong health impacts on brain, bone, and organ function. Climate change accordingly has differential impacts across groups with varying vulnerability; climate justice and food justice intersect

with gender justice and with food security and intergenerational justice.

At the same time, African production of the greenhouse gases causing global climate change is negligible in comparison with heavy emissions from industrialized countries. Poverty prevents farmers from accessing fossil fuel-hungry technologies, and they typically farm with a handhoe. The majority of African farmers accordingly have a small carbon footprint and are ill-prepared and under-resourced to adapt to environmental factors like drought and flood or less dramatic but nonetheless destructive climate impacts like unpredictable and sporadic rainfall that lead to crop failure and large postharvest losses (FAO 2008). Principles of distributive justice are thus doubly breached when those making the least contribution to climate change and reaping least of its benefits are bearing its costs disproportionately.

Global Issues in Agricultural and Food Ethics

Observed declines in agricultural yield are the result of multilayered problems including climate change, rainfall and weather events, decline in soil fertility, increase in pests and diseases, change and delay in cropping activities, decline and poor adoption of external inputs to enhance productivity, and limited individual property rights – all major impediments to investment in African agriculture (Amponsah 2009). The International Institute of Tropical Agriculture also points to lack of microcredit, minimal value-adding crop-processing activities, poor storage, food preservation, pricing, high poverty among farmers, and inconsistent agricultural policies (IITA 2007).

Causes of African food insecurity and lack of food sovereignty in the global South are not however driven only by regional environmental, political, economic conditions: neoliberal, post-colonial globalization also plays a role. Critics attribute its food crises to decades of interventions from the global North, i.e., Green Revolution projects, structural adjustment programs, regional free-trade treaties, and World Trade Organization

agricultural subsidies in developed countries (Holt-Giménez 2008, 5–6). Others point to neo-liberal policies of trade liberalization and foreign debt repayment, indiscriminate privatization of public services and goods, and the logic of capital at work in agriculture and food models (Vivas 2010). Typically, when commercial farming development projects displace subsistence farmers, for example, the latter seek employment by the former whose large-scale, mechanized production systems grow food intended for consumers in the global North – African workers go hungry producing food they cannot afford to buy. Issues in African agricultural and food ethics accordingly cannot be resolved without addressing inequities in North-South global relations.

Conclusion

The celebration of food and agriculture is common across African countries, religions, and cultures due to its importance in historical and intergenerational continuity and its role in ethnicity and ethnic identity. African food production is a significant livelihood strategy, and most agriculture is subsistence, largely practiced by women who manage the process from planting to harvesting with minimal inputs and do their own processing from field to table.

Culturally rich and distinctive food traditions in Africa have been undermined by postcolonial, neoliberal global politics and economics that have disrupted Africa's resource base and introduced large-scale, industrialized, monoculture-favoring, capital- and technology-intensive, corporate farms. Ill-conceived, if well-intentioned, development programs have led to poorly managed commercial agriculture that has damaged local environments. Global climate change increasingly exacerbates this damage, and Africa at present is in a state of agricultural and food crisis that is unlikely to improve and is already erupting into a humanitarian emergency that is globally unprecedented in scale and severity.

African issues in agricultural ethics involve labor, including child labor; gender issues,

including social inequalities, weak land tenure, and limited access to resources; environmental justice issues including distributive, recognition, and intergenerational justice; and climate justice as Africa suffers disproportionate impacts from climate change while generating comparatively small amounts of the greenhouse gases that are causing it. Increasing population, decreasing yields, and socioeconomic, political, and post-colonial issues have placed African countries on a spectrum ranging from food insecurity to the full-blown crisis currently being experienced in South Sudan. The most pressing issue in ethical assessments of African food and agriculture is mass starvation.

Introduction

“Agrarianism” refers to certain schools of thought and forms of life which regard farming and related vocations as exceptional in that farmers are independent, self-sufficient, and self-determining and work in step with nature, the local ecology, the seasons, etc. Independent yet attuned to their ecological setting, agrarian farmers think and act holistically. Working in and with nature, agrarian farmers view themselves as stewards of their ecological setting and who keep an eye on the environmental health of the area. To agrarians, city folks lead dependent, other-directed lives, artificial and out of step with nature. The agrarian life is built on trust, neighborliness, and cooperation, unlike the alienation and distrust of city life. Dwelling in stable communities, rural agrarians nurture a sense of personal identity that is rooted in place and local history and color. Moreover, Agrarianism regards tilling the soil, cultivating crops, raising livestock, producing food stuffs, etc., as transformative toils and virtue-engendering endeavors. Yes, farming is toilsome; however, agrarians deem that this very hardship engenders the farmer's traits of determination, perseverance, and know-how. Agrarianism holds that such virtues are nurtured in farmers via their

interactions with nature as they work to forge fecund order out of wilderness.

Why the continued relevance of Agrarianism? Humanity's connection with terra firma is breaking up as people flock to the cities worldwide and increasingly lead artificial, disconnected lives. In the developed nations, the few remaining family farmers feel caught between global agribusiness and big food processors. Meanwhile, city dwellers have slight awareness of the source of their food, which they know as the packaged products on supermarket shelves. In the last half century, industrialized agriculture has rapidly introduced economies of scale and cheap food for consumers; however, this productive efficiency comes at a high cost to the environment. Synthetic chemicals, such as those used as pesticides and fertilizers, can certainly improve agricultural productivity – at least in the short term – but they can also have deleterious impacts on surrounding environments as pollutants of soil, water, and the atmosphere. They can also contaminate farm products too. The widespread use of antibiotics in intensive animal production has resulted in their loss of effectiveness for disease control not only in animals but also in humans. And then there is the matter of an often reduced attention to the welfare of the animals in the production units of industrial farms.

The ubiquitous rise of these phenomena is fueling new calls for Agrarianism and agrarian values. In recent decades, people have been returning to rural lifestyles or at least greening their urban settings.

Age-Old Agrarian Views and Virtues: Classical Antiquity

The agrarian life and virtues were esteemed in classical Greece and Rome. In *Works and Days*, the Greek bard Hesiod depicted the rural life. *Works and Days* celebrates the dignity, toil, and generosity of the farmer and teaches prudential morality. Toil steadfastly, incessantly! Grow your bounty step by step! Cooperate and share with thy neighbor; thy kindness shall be returned in kind! (Robinson 1968, pp. 20–21). Xenophon

and Aristotle lent support to Hesiod's agrarian virtues. In classical Rome, such writers as Cato, Pliny, and Cicero and poets as Horace and Virgil celebrated the agrarian life and values. Horace wrote poems set on his Sabine Farm or in a country town, which express the farm's bounty, beauty, and proximity to nature. Virgil's *Georgics* celebrates the piety of country life in sections on field crops, trees, livestock, and bees. Virgil offers didactic teachings about farming but with wider horizons. In the *Georgics*, he affirms moral tenets and philosophic views of wide import. Virgil's farmer stands for broader humanity. For him, farming is the premier human activity across the world. Virgil laments the disappearing solitary farmer who worked his own land as a falling away of humanity from its core vocation.

Classical China

In classical China, the Confucian virtues reflected the agrarian society but were the virtues of the feudal landlords rather than of those who tilled the soil. Thus, in Confucius' *Analects*, rural folk question his wisdom and quixotic ideals. And, in the *Mencius*, followers of the school of Tillers (*Nongjia*) question Mencius' separation of ruler and ruled, advocating a rural egalitarianism. The Tillers held that society was born with the development of farming and that healthy societies were grounded in humanity's propensity to till the soil together.

The Tillers' ideal of rulership was adopted from the agrarian sage, Shennong, renowned for identifying herbs, crop plants, and medicinal and poisonous plants and for teaching people how to farm. Hence, Tiller kings worked the fields alongside the people, while their queens wove fabrics and performed domestic tasks with the other women. The Tiller kings did not receive state funds but earned money from working their own fields. The Tillers disputed the Confucian notions of administrative elites and division of labor, arguing that egalitarianism and self-sufficiency were the proper grounds of a stable society. Disputing also the idea of stratified prices of basic goods, they insisted that food staples, regardless of

quality or demand, should be sold at fixed prices to ensure fair distribution. A follower of the school of Tillers once told Duke Teng, “A worthy ruler feeds himself by plowing side by side with the people, and rules while cooking his own meals. Now Teng, to the contrary, possesses granaries and treasures, so the ruler is in effect supporting himself by oppressing the people” (Lau 1970, 100f; Graham 1979).

European Echoes

Physiocracy, an early economic theory that stressed land and agriculture, arose in the eighteenth-century France. Its leaders, Francois Quesnay and Anne-Robert-Jacques Turgot, were influenced by Chinese agricultural policy. Quesnay advocated such a *laissez-faire* agrarian policy for France. The Physiocrats stressed rural labor and extractive industry, including grasslands, pastures, forests, mines, and fishing, as sources of national wealth. They saw the consumption of farm surplus as the basis of trade and industry, which themselves produce no net product. Naturalists, the Physiocrats believed that if the human order were brought into attunement with the natural order, society would be healthier. They not only stressed agriculture in economics but rejected the shallowness and artifice of urban life and praised natural living, especially as farmers.

Modern Western Agrarianism too held that wealth originates from the land and that farming is the foundation of other vocations. Modern Agrarianism drew on John Locke, who asserted that those who work the land should be its rightful owners in *Second Treatise of Civil Government* (1690). This labor theory of value influenced Thomas Jefferson who shaped how nineteenth-century American homesteaders viewed the ownership of their farms. In a letter to John Jay, Jefferson wrote, “Cultivators of the earth are the most valuable citizens. They are the most vigorous, the most independent, the most virtuous, & they are tied to their country & wedded to its liberty & interests by the most lasting bonds” (1785; Jager 2004, 12).

Agrarianism was a leading theme in the eighteenth-century British georgic poetry. The

poets Stephen Duck, Mary Collier, and Thomas Gray sang of the hardships as well as the virtues of farm life. They followed Horace in exploring the themes of town vs. country and the happy man, but Virgil’s *Georgics* held center stage for them as a model for expressing agrarian life and virtues poetically. In the late eighteenth and early nineteenth centuries, European Romantics stressed the individual and viewed nature as a spiritual force. At a time when the wilderness was vanishing across Europe, they identified “nature” with the remaining mitigated wilderness of farm fields and woodlots. To the Romantics, farmers lived in touch with nature – positioned to experience moments of transcendence from the mundane world.

American Echoes

In eighteenth-century America, Agrarianism was espoused by Benjamin Franklin, Thomas Jefferson, John Taylor of Carolina, and others. Mid-nineteenth-century voices included the transcendentalists Ralph Waldo Emerson and Henry David Thoreau. The next wave featured philosopher Josiah Royce, land reformer Henry George, botanist Liberty Hyde Bailey, writer Hamlin Garland, followed by the Southern Agrarians of the 1920s and 1930s, and novelist John Steinbeck. Volumes 3 and 5 of *The Economic History of the United States* cover the conditions and practices of agriculture in nineteenth-century America: *The Farmer’s Age: Agriculture 1815–1860* by Paul W. Gates and *The Farmer’s Last Frontier: Agriculture 1860–1897* by Fred A. Shannon.

In 1930, the Southern Agrarians published “A Statement of Principles” asserting:

a Southern way of life against . . . the prevailing way; and . . . agree[ing] that the best terms in which to represent the distinction are . . . Agrarian *versus* Industrial. . . . Opposed to the industrial society is the Agrarian. . . . Technically, . . . an agrarian society is one in which agriculture is the leading vocation, whether for wealth, for pleasure, or for prestige – a form of labor that is pursued with intelligence and leisure, and that becomes the model to which the other forms approach as well as they may. But an agrarian regime will be secured

readily enough where the superfluous industries are not allowed to rise against it. The theory of Agrarianism is that the culture of the soil is the best and most sensitive of vocations and that therefore it should have the economic preference and enlist the maximum number of workers. (Davidson et al. 2006.

Prominent agrarian voices in the mid-twentieth century include Aldo Leopold (1887–1944) and Rachel Carson (1907–1964). Leopold saw the farm ethically as a place of conservation. He believed that harm was done to ecosystems out of the farmer's misguided sense of private ownership, which had eclipsed the idea of rural community. Following Thoreau, he expanded the idea of community to include the environment and the farm. Leopold wrote several essays and *A Sand County Almanac* (1949). Carson alerted the world to the environmental threat posed by DDT and other pesticides in *Silent Spring* (1962). She proposed using biological and ecological means of pest control. *Silent Spring* provoked debate over environmental ethics, government regulation of industry, and the appropriate uses of technology. Carson extended some of Leopold's ideas about land ethics, such as human duties to the natural ecology.

American Neo-Agrarians

Recent agrarian thinkers are dubbed “neo-Agrarians.” Prominent among them are Wendell Berry, J. Baird Callicott, Paul B. Thompson, Gene Logsdon, Eric Freyfogle, and others. They view the world through green tinted glasses. They espouse the old agrarian views while tackling new fields, such as biotechnology, environmental studies, and new technologies on the farm. Wendell Berry has written books, essays, and poems on farm life, rural community, connection to place, sustainable agriculture, etc. He is a public defender of agrarian values. J. Baird Callicott applies a Leopoldian ethic to the problem of global climate change. He advocates a multifaceted non-homocentric environmental ethic that accords with Leopold's assertion that “A thing is right when it tends to preserve the integrity, stability, and beauty of the biotic community. It is

wrong when it tends otherwise” (Leopold 1949). In Callicott's view, an effective environmental ethic must address real-life ecological concerns in a holistic way. Paul B. Thompson brings the tools of philosophic analysis and ethics to bear in examining the environmental significance of farming in books and articles, such as *The Spirit of the Soil* (1995). In *The Agrarian Vision* (Thompson 2012), he focuses on sustainability ethics and agrarian philosophy. In several books, Eric Freyfogle explores ways for humanity to live sustainably by responsibly attuning human activities and communities to the environment.

Neo-Agrarianism attempts to incorporate the agrarian values of other traditions, as well as new knowledge to deepen and broaden its view. The past offers lessons, but in the global village today, neo-Agrarians must adopt an inclusive vision for the future. In planning the new rural community, they must register twenty-first-century global trends and society yet stay committed to sustainable living. As humanity is a part of nature, neo-Agrarians constantly remind humanity of the need to integrate human activities with natural processes.

Signs of New Life

Despite the environmental challenges posed by industrial and corporate agriculture, there are signs of new and deepening agrarian awareness. In the developed world, there are biodynamic agriculture, permaculture, and growing demand for organic food sourcing, and in the developing world, there is an upsurge of peasant labor, rural women, youth, and indigenous peoples' movements, which are autonomous, multicultural, and free of divisive ideological, political, and economic commitments. Such movements were inspired by the Chicano farm worker organizer César Chávez of the 1960s. The new farm labor movements emphasize peasant or family farming based on sustainable practices using local resources and following local traditions. Such peasant farmers draw on their heritage, utilize local resources, and produce organic food stuffs with few external inputs. Their production tends

to be aimed locally for family and community consumption and domestic markets.

Biodynamic agriculture is inspired by the work of Rudolf Steiner, especially his insistence on maintaining (1) sustainable soil fertility and (2) the relationship between plant growth and cosmic rhythms. Biodynamic agriculture stresses a holistic, spiritual understanding of nature and human life and thus aims at self-sufficiency in compost, manure, and animal feed, with little minimal external and nonnatural input. The keynote of biodynamic landscaping is preservation of ecological diversity. Biodynamic methods are being adopted worldwide. For example, tea plantations in Darjeeling are retiring chemical fertilizers and returning to traditional worm compost, manure, and biodynamic floral preparations.

Permaculture involves the construction of sustainable human living spaces in keeping with local topography. It draws upon the diversity, stability, and resilience of natural ecosystems in developing sustainable solutions to the problems of one's living environment. It stresses cooperation with nature and care for the earth and people. Its holistic, integrated approach emphasizes contemplation and minimal impact. Permaculture regards human beings as nature's kin, related to all life in the biosphere. It encourages people to revere the mystery of existence and approach nature with humility. Permaculturists propound ethical action principles, such as (1) conserve, use only what is needed; (2) stack functions, get multiple outputs from each element in the system; (3) repeat functions, meet each need variously; (4) reciprocate, use outputs of one element to meet needs of other elements in the system; (5) appropriate scale, make output match need scale; (6) diversify, use multiple elements to increase resilience; and (7) donate surplus, do not hoard.

Rural Trends in East Asia

In Postwar East Asia, land reform and land to the Tiller movements led to a resurgence of the independent farmer. In the 1950s, agriculturists from the United States visited various East Asian countries to teach the latest farming methods and

introduce efficient, fair marketing. Following Thomas Jefferson, the Neo-Confucian thinker Xu Fuguan (1902–1982) argued that such independent farmers could serve as the pillar of democratic development in East Asia. However, following the success of land reform, cash-strapped regional governments took advantage of the surpluses created by the farmers to prime the well for industrialization, which in turn drew national attention and funds away from the farming sector. In consequence, the hearts of the next generation were set on elegant city life in modern industrial society. In recent decades, regional governments have started to realize the importance of the agriculture and food sector. Moreover, some people are beginning to return to the countryside for respite from the ubiquitous crowds, traffic, noise, and pollution of city life in East Asia.

Throughout East Asia, the age-old peasant societies have vanished, and rural societies have become less dependent on farming. Economic challenges have been pressing rural societies to diversify their economies. Dedicated farmers are increasingly in the minority. Even rural farm labor is in short supply. Though farm labor was abundant in the recent past, it is no longer easy to recruit farm hands. Rural occupations have diversified because farming cannot support the rural population. Additionally, rising farm operating costs are spearheaded by expensive farm machines, advanced seed, fertilizers, and pesticides as well as by the training and education needed for advanced farming. Living costs have risen, as well, due to new lifestyle trends introduced by globalization. Industrialization also pushes these changes in rural society, and urbanization is penetrating rural society through regional urban centers that relay global trends. To survive, regional rural communities have to be made more attractive to the youth. Local community leaders and boosters brainstorm not only about developing industries but about attracting new businesses to create work opportunities. Still, agriculture remains a key factor.

In Taiwan, joining the WTO caused several crises in the agricultural sector, primarily from the curtailment of rice subsidies and other price supports. Some farmers turned to raising niche

and value-added crops to make up for higher overhead. A major innovation has been organic rice production. Over time, the organic farmers in Taiwan have come to appreciate the ethical dimension of their activity and now practice sustainable farming just because “it is the right thing.” In addition, enterprising farmers are sidestepping the traditional food marketing system, which favors the middleman, to establish their own brand names, even to deliver their products directly to consumers. Some even distribute catalogs; survey consumer satisfaction, needs, and requests; and inform customers about harvest and processing schedules. Japanese and South Korean farmers are being similarly proactive and innovative.

In China, while organic crop and range livestock production are being introduced, this development is fueled more by entrepreneurs with an eye to the bottom line than by dedicated farmers who love their vocation. The entrepreneurs’ mixed motives undermine consumer acceptance of Chinese organic certifications. Moreover, the ubiquitous soil and water contamination in China makes the organic crop and range livestock quests quixotic there.

The Green and Blue Revolutions

“Blue” has joined “green” as an environmental red button word. The idea of “blue revolution” recalls the green revolution of the 1960s and 1970s but refers to water in terms of fresh water supply and aquaculture. Fresh water supplies are dwindling due to a host of factors, such as melting glaciers, reduced rainfall, chemical and biological contamination of ground water as well as of lakes and rivers, accelerated desertification, etc. Fresh water supplies are dwindling just as human populations are soaring, and experts predict a huge impact to humanity and to the biosphere during the present century. Recent reports of the United Nations Environment Programme (UNEP) warn that as fresh water supplies dwindle, the world will face massive human suffering in the forms of starvation, famine, migration, violence, and possibly warfare as nations fight to secure

life-sustaining fresh water resources for their populations. In this respect, the blue revolution will include projects to increase world supplies of fresh water by a wide variety of means.

In recent decades, Indians have realized the importance of the green revolution for increasing agricultural output to overcome starvation, feed a soaring population, and improve the standard of living of rural people. Over time, it was found, however, that the green revolution had a serious impact on fresh water supplies. The experts had led the farmers to concentrate just on crop issues, especially crop output, and did not take a holistic approach and take into account local ecosystems. They took piecemeal approaches to specific problems and completely neglected such collateral issues as the quality of fresh water supplies and the health of the environment. Many farmers still utilize this blinkered approach to farming, though it may erode the fertility of the land they farm. As people realize the danger posed by the dwindling fresh water supply, farmers are increasingly encouraged to take off their blinkers and think about their crop issues holistically in terms of the water/food/energy connection. The time has come to initiate a blue-green “turquoise revolution” that takes a holistic approach to challenges and risks of water as well as of land.

Fish and shrimp aquaculture have arisen as another key facet of the blue revolution – that is, the effort to farm an array of aquatic species. As in the case of the green revolution, the blue revolution is touted as a way to feed the world’s hungry; however, blue revolution producers to date mostly aim at high-end seafood production for the affluent consumers rather than at mass seafood production to feed the poor.

While salmon and shrimp farms are most prominent forms of aquaculture, aquaculture includes a wide variety of operations, aquatic species, and management systems. Aquaculture is not limited to just one form of industry or set of operations, so it is difficult to manage or regulate. While there is constant interest in expanding aquaculture operations and production, new models of aquaculture development are needed which would be ecologically attuned, incorporate technical ecosystem design and ecological

principles, and be adaptable to local environmental settings. Aquaculture on any scale makes a significant environmental impact, as does land agriculture. Future aquaculture operations must be ecologically friendly, that is, enhance natural fisheries, reclaim broken ecosystems and habitats, and offer a holistic vision of the coastal areas. With new forms of aquaculture development that incorporate environmental planning, humanity could become stewards rather than destroyers of the world's coastal aquatic ecosystems. In short, to succeed, the blue revolution must be greened and turn turquoise.

Some Problems with the Blue Revolution

Aquaculture is often touted as offering the promise of a blue revolution in fish production. Like agriculture's successful green revolution, aquaculture is promoted as a way to increase food production from the sea. To date, however, industrial aquaculture has wrought serious environmental and social problems. As local ecosystems and species have been adversely impacted, indigenous coastal peoples have lost their food supplies, livelihoods, even their homes and cultures, to industrial aquaculture. Meanwhile, the affluent consumers of the fish products are unaware of the negative effects of farming the sea.

In recent decades, shrimp aquaculture has spawned long-term environmental and social problems, including degradation and loss of coastal resources, tainting of waters from nearby estuaries and coastal bays, and loss of fish breeding and nursery grounds to shrimp farm operations. The shrimp aquaculture farms disrupt coastal ecology. Precious mangrove forests and diverse ecosystems are cleared to make way for the farms. Crucial coastal habitats, including mudflats, sea grass beds, and coral reefs, are degraded or despoiled. And waterways and underground aquifers are increasingly contaminated due to the farms. Ironically, shrimp farming uses clean fresh water but causes water pollution, often fouling its own nest. The use of antibiotics, pesticides, and water additives, combined with pond residues of unused feed and waste, leads to disease and pond

closures. Shrimp farms, like other forms of aquaculture, create risks of genetic contamination and reduced biodiversity. Accidental release of farm shrimp or fish can negatively impact the native species. Moreover, a key factor impacting local fisheries is selective catching of wild shrimp larvae to restock the shrimp farm ponds. As global fisheries decline, the shrimp fry fishery for aquaculture has a high bycatch rate of up to 20 lb of fish lost per pound of shrimp larvae caught. Vital habitats have been lost for fish, mollusks, and crustaceans, as well as for birds, migratory species, and endangered species near the shrimp farms.

In Asia, the average aquaculture farm lasts for only a few years before pollution and disease problems cause pond closures. Overstocking and overuse of feeds and water additives are practiced. The key problem is that shrimp farming is being conducted even though the technology is still in the R&D phase. Serious problems remain to be solved. The shrimp product itself contains health risks. The farmers' use of antibiotics, pesticides, and feed additives raises serious questions for consumers. Some of the antibiotics used in shrimp farms are close to antibiotics used to treat human diseases. Due to public concern over health risks, Japan has identified over fifteen antibiotics used in shrimp farms and has banned shrimp products with these antibiotics.

The Ethics of Eating

People the world over are increasingly concerned about the rapidly expanding degradation of the environment and biosphere. And they are becoming aware of the environmental implications of farming operations and practices and, by extension, of their eating choices. Farming activities occupy up to 50% of the earth's land surface and exert serious impacts on the environment. Additionally, vast numbers of the world's poor people farm marginal lands and waterways and in hard times turn to global charities to carry on. Global hunger and environmental ethics concerns thus intersect, as environmental degradation erodes the livelihood of the poor.

The sustainable agriculture movement took shape during the 1980s in the United States, connecting the rural economic crisis with the environmental problems of agrichemicals and soil pollution. Sustainable agriculture promotes farming practices that sustain local ecosystems and topsoil as a necessary alternative to the industrial farm model. It embraces not only environmental protection but social fairness by arguing for sustainable farming methods and for the well-being of farm hands and consumers. Social fairness includes economic equity for farm hands as well as access to basic food stuffs for the poor. A popular way to practice sustainability ethics is to buy locally grown food in season from the producer, for example, at farmer's markets.

The local food movement advocates setting up locally based food economies that encourage sustainable food production to enhance the environmental and public health of a locale. It defends local economies by buying locally produced food products and services rather than those delivered by distant giant food companies. In short, the local food movement encourages consumption of local food stuffs and use of reliable short supply chains.

Local food systems are the key to implementing local food values. The concept of local food systems covers how food is produced and reaches consumers, as well as consumer food options. It includes the notions of food chain and food economy. Local food systems stand in stark contrast to the industrial corporate model of food systems wherein producers and consumers are often widely separated. Local food systems reflect close relationships between producers, retailers, and consumers in particular locales. The local food systems are nuclei working to ensure the ecological and social sustainability of local communities. "Local" in this discourse is measured in geographic distance but is also understood in terms of basic ecological units demarcated by climate, soil, watershed species, and local agriculture practices. These units are called ecoregions or foodsheds, that is, locales where food is produced and consumed.

Why should people eat locally? A community supported agriculture system enables consumers to support local farmers; obtain fresher, healthier

food; and better understand how the food is grown. Local eating also fosters relationships between farmers and consumers. Shopping at farmers markets often features health sessions, dissemination of information, and a space for community engagement. Local farmers' markets build community sociability and maintain local traditions while creating unique senses of community. Locally grown goods do not need to be transported cross-country or constantly cooled in large refrigeration units. Besides, locally grown foods are better because of the farms' smaller size. Local farms produce far less waste in quantity and concentration than do factory farms, which seriously pollute the surrounding air, land, and waterways. Locally grown foods support free-range or pasture-grazing farming methods, decreasing the need for factory farms, with the accompanying waste and its effects on surrounding areas.

With the rapidly increasing world population, efficiency is crucial to reducing the widespread malnutrition today. In this respect, the questionable effectiveness of a local food system is challenged for reduced productivity per farmer that might result in decreased food supply as well as the need for agricultural expansion into new lands. Such expansion, a major contributor to global deforestation, is a huge problem, especially in regard to greenhouse gases and biodiversity. Further research on the difficulties of implementing local food systems is needed to find ways to avoid these side effects associated with small farm production.

Summary

In closing, the question arises, why Agrarianism today? Humanity's connection with the living earth is breaking up as people flock to the cities to lead artificial, disconnected lives. In the developed nations, the few remaining family farmers feel caught between giant global agribusiness and big food processors and retailers. Meanwhile, city dwellers have passing awareness of the source of their food, which they recognize as the packaged products on supermarket shelves. In the last half century, industrialized agriculture introduced

economies of scale and delivered cheap food for consumers; however, this productive efficiency comes at a high cost to the environment. Moreover, industrial farm operators often neglect livestock welfare and depend on dangerous chemicals, which damage ecosystems and contaminate soil, water, and even food. The ubiquitous rise of such phenomena is fueling new calls for Agrarianism and agrarian values. And, in recent decades, people have begun to rediscover rural lifestyles or at least green their urban settings. This is important, for the survival of humanity will depend on people's acceptance of sustainable agrarian values and practices to reduce climate change and restore the health and well-being of Mother Nature on whom human life depends.

[Agricultural and food products in regional and bilateral trade agreements](#); [Preferential market access for agricultural and food products](#); [Reciprocal](#); [Unilateral preferential access for agricultural and food trade](#)

Introduction

The primary agricultural sector has been generally characterized by considerable governmental interventions through domestic support and international trade policies (Schmitz et al. 2010). Such governmental interventions are often extended to cover selected processed food products, particularly those that are deemed to be sensitive. The sensitivity of the primary agricultural sector is mainly associated with food security issues. It also stems from the influence of farmers' organizations that persuade governments through lobbying activities to implement protectionist policies vis-à-vis foreign products and to adopt price and income support schemes. Although these policies are expected to affect consumers and taxpayers, they are normally justified by ethical arguments regarding the well-being and competitiveness of domestic agricultural producers. These arguments are often countered by questioning the ethical validity of various protectionist policies in the first place. In this context, there are two evident ethical questions that can be addressed when comparing the outcomes from trade liberalization schemes and those from protectionist policies. First, to what extent is the reallocation of benefits between few producers (gains from protectionism) and lots of consumers (gains from trade

liberalization) ethical? Second, is it ethical to weigh the welfare of one group more than the welfare of another group when total welfare goes up with free trade policies or goes down with protectionist policies? These ethical questions are relevant through various trade liberalization policies, including preferential and multilateral trade agreements.

Preferential trade agreements (PTAs) are preferential market access agreements for international trade between two or more member countries relative to nonmember countries. Preferential market access policies are normally expressed through reductions or eliminations of tariff barriers and also through various types of nontariff trade preferences such as trade facilitation practices over customs administrations for imports originating from member countries. PTAs often comprise regulations that manage trade between member countries such as Sanitary and Phytosanitary (SPS) provisions, safeguard measures, Technical Barriers to Trade (TBT), and provisions on domestic support and export subsidies. In some cases, PTAs encompass common regional sector-specific policies, such as the Common Agricultural Policy (CAP) of the European Union (EU).

Policy barriers applied on agricultural and food trade remain generally higher than those applied on manufactured products' trade. Consequently, the implications of PTAs for agricultural and food trade are expected to be different compared to those prevailing for manufactured products' trade. For example, the implementation of a comprehensive regional free trade agreement is expected to have a higher impact on intra-regional agricultural and food trade compared to trade in manufactured products. Many PTAs have more limited degrees of market access preferences for sensitive agricultural and food trade compared to trade in manufactured products. The vertical linkages between the primary agricultural sector and the food processing sector generate diverse implications of PTAs for the patterns of trade and industrial growth. Also, PTAs' treatment of domestic agricultural support policies, the prevalence of various SPS and TBT measures, and the regularity of provisions on nontariff trade policies

further distinguish the implications of PTAs for agricultural and food trade.

There are several types of PTAs that are determined according to the number of member countries, geographic location, and the implementation of reciprocal versus unilateral preferences. One prominent type of PTAs is plurilateral, involving several countries. Most of these plurilateral PTAs cover countries located in geographic proximities. Such agreements are commonly termed regional trade agreements (RTAs). Prominent examples of RTAs include North American Free Trade Agreement (NAFTA) in North America, *Comunidad Andina* (CAN) or the Andean Community and *Mercado Común del Sur* (MERCOSUR) or the Common Market of the South in South America, *Mercado Común Centroamericano* (MCCA) or the Central American Common Market in Central America, Association of Southeast Asian Nations (ASEAN) in Asia, EU and the European Free Trade Association (EFTA) in Europe, Common Market for Eastern and Southern Africa (COMESA) and Southern African Development Community (SADC) in sub-Saharan Africa, Greater Arab Free Trade Area (GAFTA) and Gulf Cooperation Council (GCC) in the Middle East and North Africa, and the Caribbean Community (CARICOM) in the Caribbean region.

Many PTAs are bilateral trade agreements (BTAs), which are trade agreements between two distant or two neighboring countries. Examples of BTAs include the United States-Chile Free Trade Agreement and Egypt-Turkey Free Trade Agreement. BTAs are often realized between one regional trading bloc and one country. Examples of such BTAs include the EU-Chile Free Trade Agreement and ASEAN-China Free Trade Agreement. RTAs and BTAs are normally characterized by reciprocal preferences in the sense that member countries offer each other preferential market access. There are some PTAs that are unilateral in nature and are mainly intended to enhance the market accessibility of various products, particularly primary agricultural commodities, from developing countries and Least Developed Countries (LDCs) to the markets of developed countries. The EU's Generalized System of Preferences (GSP) and the Development Cooperation

between the EU and the African, Caribbean, and Pacific Group of States (ACP) are prominent examples of such PTAs.

There are also several types of RTAs that are classified according to the extent of market integration. Free trade areas depict the basic stage of market integration. Member countries offer each other preferential market access, but maintain their own external tariff schedules vis-à-vis imports from nonmember countries (e.g., NAFTA). Customs unions represent the next stage of market integration where member countries adopt common external tariff schedules vis-à-vis imports from nonmember countries (e.g., MERCOSUR). The extent of market integration is further promoted through Common Markets where factors of production have free intra-regional mobility (e.g., the former European Economic Community). Market integration culminates at Economic Unions where member countries harmonize their macroeconomic policies. The EU is often considered as one prominent example.

Preferential and Multilateral Trade Agreements

The sensitivity of the primary agricultural sector has resulted in slow progress in multilateral agricultural trade negotiations through the World Trade Organization (WTO), which was formed in 1995 as the successor to the General Agreement on Tariffs and Trade (GATT). Multilateral negotiations over global liberalization schemes for agricultural trade were initiated through the GATT's Uruguay Round of multilateral negotiations (1986–1994) and resulted in the Uruguay Round's Agreement on Agriculture (URAA). The subsequent negotiation rounds over the draft modalities of the Doha Development Agenda (DDA) for agriculture have been difficult. The resulting sluggish progress in multilateral trade negotiations over agricultural and food trade have further emphasized the role of PTAs as alternative international market access policies for agricultural and food trade. PTAs often include countries that share many common economic interests, and

hence, they are easier to realize compared to multilateral trade agreements.

The proliferation of PTAs could be associated with some ethical concerns when some countries are being “left out” from major influential PTAs. These countries could be then forced to ride the waves and make significant concessions when engaging in preferential agreements. PTAs are sometimes considered stumbling blocks since they can diffuse the pressure on the global trading system to reach multilateral trade agreements which could be beneficial to many groups in many countries. Consequently, PTAs could contribute in delaying the realization of multilateral agreements for agricultural and food trade through the current WTO's DDA and could adversely or favorably affect the agricultural and food sector and national welfare in many countries. Alternatively, PTAs could be perceived as building blocks toward a globally liberalized trading system which parallel the WTO's attempts through multilateral negotiations. Thus, progress in PTAs could ultimately lead to freer global trading systems and would arguably enhance global welfare in the long run. This outcome is consistent with many ethical considerations when it ultimately improves the well-being of many groups in many countries. However, some ethical concerns could be also addressed since a freer global trading system could unfavorably impact a wide range of agricultural and food producers who could incur significant losses from increases in foreign competition and could face adversity through the process of adaptation to a globally liberalized market.

There could be some supplementary ethical considerations associated with membership in PTAs when carrying out multilateral trade negotiations. RTAs are expected to strengthen the negotiation positions of member countries through the WTO's DDA multilateral negotiations. A member country that does not individually have a strong position through these negotiations can better voice its interests through a regional trading bloc. However, the dominant negotiating positions of major regional trading blocs could occur at the expense of the interests of other (mainly developing) countries that are left out. This outcome could negatively affect many groups in these countries.

Characteristics of PTAs

The depth and breadth of trade preferences exhibit a wide variation across different PTAs. Some PTAs cover trade in virtually all products and grant free market access. Other PTAs cover some products and/or offer reduced preferential trade barriers to member countries relative to non-member countries. Members of the WTO are required to maintain nondiscriminatory trade policies vis-à-vis all other members. These non-discriminatory policies are expressed through the principle of Most-Favored Nation (MFN) treatment, where a preference given to one country should be extended to all other countries, and through the principle of national treatment of imported products. However, there is an exception through Article XXIV of the GATT where countries are allowed to form PTAs, provided that they do not increase barriers on imports from other WTO member countries. This Article also requires the elimination of trade barriers on “substantially all trade” between PTA member countries. The ambiguity of “substantially all trade” has often led to various interpretations. In some cases, limited depth of trade preferences and incomplete product coverage of PTAs could be viewed as being inconsistent with the requirements outlined in this Article.

There are many agricultural products that are deemed to be sensitive because of lobbying activities (supply-managed products in Canada and the United States), cultural reasons (e.g., rice in Indonesia and Japan), or food security reasons (e.g., wheat in Middle Eastern countries). Some PTAs set limitations on preferential access for several sensitive agricultural and food products. For example, supply-managed products in Canada, such as dairy products, eggs, and poultry products, remain protected vis-à-vis imports from other NAFTA member countries. Meanwhile, several sensitive agricultural products in the United States (e.g., cotton, dairy products, and peanuts) are shielded against competition from other NAFTA member countries. Member countries of SADC implement trade barriers on intra-regional trade flows in many sensitive agricultural products, namely, cereals, cotton, and dairy

products. Member countries of MERCOSUR have individual lists of sensitive agricultural products that are exempt from duty-free market access and from the implementation of common external tariffs. Also, ASEAN member countries exclude rice and other sensitive agricultural products from preferential access through the exceptions granted under the Common Effective Preferential Tariff (CEPT) scheme. Some PTAs comprise Tariff Rate Quotas (TRQs) applied on trade among member countries for sensitive agricultural products. TRQs have a 2-tier tariff structure where a maximum level of imports is taxed at a low in-quota tariff rate and additional imports are subject to an over-quota tariff rate. For example, the United States-Chile Free Trade Agreement contains TRQs applied on imports of several agricultural commodities (e.g., beef, cotton, and dairy products). These limitations could favor domestic producers' well-being. However, they could come at the expense of efficient allocation of resources and foreign producers' and consumers' benefits.

The extent of trade preferences of PTAs for member countries can be examined by contrasting trade barriers applied on trade flows between member countries (e.g., preferential tariffs) to trade barriers applied on imports from non-member countries (e.g., MFN tariffs). For example, the applied MFN tariff barrier of the EU bloc on beef imports from nonmember countries is estimated to be equivalent to an ad valorem rate of 77% in 2005, while imports from member countries have a duty-free market access (Ghazalian et al. 2011). Mexico applied an MFN tariff rate of around 20% on beef imports compared to a duty-free market access for beef imported from NAFTA member countries (Ghazalian et al. 2011). Also, the common external applied MFN tariff rates of MERCOSUR on imports of maize (excluding seed imports) and on imports of common and durum wheat were 8% and 10%, respectively, compared to a duty-free intra-regional market access (United Nations Conference on Trade and Development 2012). Naturally, some ethical issues could be addressed when larger tariff gaps between MFN and preferential access rates prevent efficient producers in nonmember countries from reaching markets of

regional blocs and give advantage to less efficient producers in member countries.

PTAs often apply Rules of Origin (ROO) when conferring preferences for agricultural and food trade between member countries. As discussed in Fulponi et al. (2011), there are variations in ROO criteria for products to be considered having originated from member countries. ROO requirements could include a stringent criterion that agricultural and food products should be wholly produced in member countries to benefit from preferential access. They could also include de minimis criteria which allow certain percentages of agricultural and food products to be produced in nonmember countries. The ROO policies are commonly associated with free trade areas where nonmember countries have incentives to access the regional bloc through the member country that has the lowest tariff rate. Such practices are often termed “trade deflection.” Consequently, ROO policies could be justified since they are applied by member countries as preventive measures to trade deflection practices. However, stringent applications of ROO measures could raise concerns for some. This is because they could be implicitly used as TBT against efficient producers in nonmember countries along the supply chain, favoring domestic producers in member countries. There are some supplementary deadweight losses that are associated with complex systems of ROO. In this context, the “spaghetti bowl” phenomenon could prevail for agricultural and food trade where ROO policies of overlapping PTAs distort trade patterns and generate important transaction costs (Bhagwati 1995).

The implementation of the mandatory Country of Origin Labeling (COOL) program in the United States, which took effect on March 16 of 2009, has disturbed Canada’s and Mexico’s exports of many agricultural products to the United States (Carlberg et al. 2009). It has arguably lessened the magnitude of preferential market access provisions of NAFTA for these products. COOL regulations require retailers to provide mandatory labels on certain agricultural products (e.g., beef, chicken, lamb, pork, and fresh and frozen fruits and vegetables) indicating the source country. For meat commodities, these labels should indicate

the countries where the animals are born, raised, and slaughtered. The labels indicate product of the United States when all three stages take place in the United States. For the proponents of this program, these labels are ethically defensible since they are intended to have better informed consumers regarding the attributes of the purchased products and to enhance food safety along the supply chain. However, COOL programs are perceived by some as an implicit TBT which confers an advantage to domestic producers. This mandatory labeling requirement has particularly impacted the Canadian meat industry. In many cases, producers and processors in the United States along the supply chain would incur significant costs in establishing separate lines of production to segregate primary products according to their countries of origin. Consequently, an integrated supply chain where all stages of production occurring in the United States would circumvent these segregation costs (Carlberg et al. 2009).

The extent of nontariff preferences is generally more difficult to evaluate without empirical analysis. One of NAFTA’s nontariff preferences for Canadian beef and pork exports was the recognition of Canada’s inspection certificates by the United States (Veeman 1994). Nontariff preferences can be also implicitly generated when restrictive nontariff trade policies are applied on imports from nonmember countries. For example, the EU import restrictions on hormone-treated beef and genetically modified organisms (GMOs), which are common features in agricultural production of many major exporting countries (e.g., Australia, Canada, and the United States), have indirectly magnified the value of regional preferences for EU producers. Promoting food safety and conveying information on the process of production and on products’ attributes to consumers conform arguably well to various ethical standards expressing consumers’ rights to food information and safety. However, these policies are controversial since they are often believed to act as disguised supplementary TBT vis-à-vis foreign producers.

Many PTAs have SPS and TBT provisions that oversee trade between member countries. They often include harmonization or recognition of

standards for agricultural and food products. These provisions could potentially act as implicit nontariff preferences for member countries vis-à-vis nonmember countries which have their conventional standards unrecognized or different than those accepted within the preferential trading bloc. Failing to recognize foreign standards could be incompatible with ethical norms when purposely used as implicit TBT against nonmember countries. In some other cases, SPS and TBT provisions of PTAs are associated with restrictive measures that could lessen or even eliminate the significance of trade preferences between member countries. For example, the United States implemented restrictive SPS measures on cattle and bovine meat imports from Canada following the discovery of Bovine Spongiform Encephalopathy (BSE) in Canadian cattle farms in 2003. Such intra-regional SPS and TBT measures often operate as food safety policies. However, in some other cases, they could be considered as implicit barriers favoring domestic producers by lessening import competition from other member countries.

Implications of PTAs

Free trade policies are often associated with increases in trade flows and positive overall welfare implications. They could, however, adversely impact some groups through the process of adjustment and could bring about some ethical issues. In this context, Palmetter (2005) discussed the general aspect of free trade through various ethical theories, underscoring the costs of protectionist policies vis-à-vis losses incurred in some segments from free trade.

The evaluation of the implications of PTAs for agricultural and food trade is commonly carried out within the conventional analytical framework that describes the effects of PTAs through the trade creation and trade diversion effects (Viner 1950). The trade creation effect implies that trade preferences induce an increase in trade levels between member countries. This effect has positive welfare implications because inefficient (higher cost) production in one member country is replaced by imports produced by more efficient

(lower cost) producers in another member country. Nevertheless, many higher-cost domestic producers facing a more intense import competition from lower-cost producers in other member countries would incur losses and would ultimately exit the market. The theoretical analysis suggests that these domestic resources would be eventually reallocated into other comparatively advantaged sectors. The process of labor reallocation could be cumbersome and many producers would be harmed by PTAs, at least in the short run. The trade diversion effect of PTAs indicates that trade is diverted from more efficient producers in nonmember countries to less efficient producers in member countries. In this context, trade diversion is associated with negative welfare implications. Furthermore, many producers in nonmember countries would be disadvantaged and could face adversity through the process of adjustment and transition from their current sector to another more competitive sector.

The net welfare implications of PTAs can be arguably assessed based on the relative magnitude of trade creation and trade diversion effects. However, such additive assessment could miss some detailed ethical issues regarding the well-being of adversely affected groups. It is commonly argued that PTAs between “natural” trading partners, which are normally located in close geographic proximity, are welfare-enhancing agreements given that trade diversion effects become less significant (Wonnacott and Lutz 1989). Various policies that facilitate (or compensate for) the reallocation of producers who are adversely affected by PTAs could enhance the case for PTAs. This is particularly relevant when trade agreements are realized between natural trading partners with limited trade diversion effects.

Preferential access schemes intended to facilitate agricultural and food exports from developing countries and LDCs to the markets of developed countries (e.g., EU’s GSP, EU-ACP Development Cooperation, and many BTAs) are often favorably regarded through the development lens. They are expected to impact the well-being of domestic producers in the beneficiary developing countries and LDCs and to enhance the growth of the agricultural and food sector in these countries.

However, there are concerns that such unilateral preferential agreements are not stemming from a pure goodwill adherence to ethical perspectives. Many unilateral preferential agreements arguably consist of binding procedures mainly intended to secure specific primary agricultural commodities that are scarce in developed countries (e.g., cocoa), and they do not always cover a wide range of agricultural products. Such agreements could force these countries into an undiversified production pattern.

There is a significant empirical literature that examines the implications of PTAs for agricultural and food trade. This empirical literature has estimated the trade creation and trade diversion effects on trade flows. However, it has not conducted comprehensive welfare assessments in general. Many empirical studies examined the implications of various RTAs for aggregate agricultural and food trade (e.g., Grant and Lambert 2008; Korinek and Melatos 2009; Lambert and McKoy 2009; Sun and Reed 2010). Several other empirical studies carried out the analyses of the effects of RTAs on agricultural and food trade at disaggregated levels (Sarker and Jayasinghe 2007; Jayasinghe and Sarker 2008; Ghazalian et al. 2011). The empirical literature has reported significant trade creation effects for several RTAs at aggregate and disaggregated levels, but it has also detected considerable trade diversion effects for some RTAs.

Several PTAs, particularly those signed between developing and developed countries, include provisions to upgrade labor and environmental standards or enforce existing ones. Adherence to these provisions could conform to labor and environmental ethical standards. For example, developing countries should satisfy many basic labor and environmental conventions to benefit from an upgraded GSP system and gain improved access to the EU market. Some preferential systems could arguably generate a “race to the bottom” when they do not include labor and environmental provisions. There are ethical concerns when the formation of RTAs leads to the deterioration of domestic labor regulations due to increases in market competition levels (Häberli et al. 2012). Also, competition from lower-wage

member countries could create various ethical considerations for the labor market within the regional trading bloc.

Lastly, RTAs could enhance regional food security by reducing fluctuations in output available in the market and by stabilizing prices (Josling 2011). This positive outcome is ethically relevant especially in the case of RTAs composed of developing countries (e.g., COMESA) where food security remains a major issue for a large proportion of the population. Also, PTAs could result in dynamic gains through the occurrence of flows of knowledge and information between member countries (Josling 2011), particularly from highly competitive agricultural and food sectors in some member countries to agricultural and food sectors in other member countries.

Summary

Membership in a PTA can affect national economic interests in different ways. It can strengthen countries' positions in international negotiations. Alternatively, it can overshadow their individual economic interests, particularly when their influence is limited within the PTA compared to other member countries. Furthermore, countries which are left outside major influential PTAs could be unfavorably impacted and could be forced to make significant concessions. Several segments in such countries could be negatively affected, raising ethical concerns.

The characteristics and implications of PTAs for agricultural and food trade encompass several economic and ethical considerations. The use of SPS and ROO measures and the implementation of various agricultural and food standard policies through PTAs could be favorably regarded when associated with the declared food safety concerns along the supply chain and with the rights of consumers to product and process information. Hence, they can be perceived as being ethically consistent with the rights of consumers to food safety and food information. However, these measures could be arguably used as implicit TBT to favor domestic producers and could eventually

affect the well-being of producers in other member and nonmember countries.

Trade creation effects of PTAs are expected to promote efficiency since lower-cost production replaces higher-cost production within the preferential trading bloc. However, trade creation effects also mean that higher-cost producers would incur losses and would eventually exit the market and that the adjustment procedure could be accompanied with adversity for these producers. Equivalent description applies to producers in nonmember countries who incur losses and exit the market due to trade diversion effects. These adjustment procedures could generate some significant ethical concerns.

In theory, some of the gains realized through PTAs could be redistributed to the adversely affected producers through relevant policies. This would alleviate the ethical concerns about the economic distress faced by these producers. In practice, such policies may be difficult to implement and could generate considerable deadweight losses to the economy. Hence, some attempts to correct one ethical issue could generate another one.

Finally, PTAs could lead to improvements in labor and environmental standards. They could also promote spillover effects expressed through the flow of knowledge and technology from a competitive sector in one member country to another member country. These events could arguably contribute in supporting the case for PTAs.

Introduction

Agricultural genetically modified organisms (GMOs) have generated substantial controversy in Europe since their introduction and commercialization in 1998. On the one hand, GMOs have been promoted as “high-yield sustainable agriculture” and as a tool for increasing the competitiveness of European agricultural systems (European Commission 2002). On the other hand, opponents have challenged the potential benefits and raised questions about their purposes, exposing competing narratives of development and diverging visions for the future of agriculture (Levidow and Boschert 2008). Critics have also highlighted the failure to account for the significance of scientific uncertainties, paradigms, and values in the development of this technology (McAfee 2003), the loss of freedom of choice for non-GM producers and consumers (Altieri 2005; Binimelis 2008), and the increasing concentration of power and capital in the hands of ever fewer social actors through the widespread implementation of patents and intellectual property rights to control the development and distribution of crop varieties (Mascarenhas and Busch 2006).

In contrast to the introduction of GMOs in many countries (such as the United States, Canada, or Argentina), the initial resistance towards GMOs in Europe was so widespread, vocal, and robust that it resulted in a *de facto moratorium* on new GMO approvals in the European Union (EU) from 1999 until 2003. This moratorium lasted until new and specific legislation on key aspects of GM regulation (e.g., risk assessment processes and labeling requirements) was put into place. These controversies also crystallized, both in political and technical terms, into a debate on the concept of “coexistence.” This concept was first introduced by the European Commission in 2002 and expressed the desire to create a system in Europe in which there was “freedom of choice” among different agricultural practices, without excluding GMOs. It was also a response to the, at the time, emerging concerns about admixture between GM, conventional, and organic crops.

The potential for the different types of crops to become mixed (and the importance of having such

a mixture be detectable and avoidable) was especially relevant for organic agriculture, as there is worldwide consensus among organic farmers and certification bodies that GMOs are excluded from organic farming (IFOAM 2002). In fact, this consensus was initially incorporated into the EU norm concerning organic food and feed production (Council Regulation [EEC] No. 1092/91). However, and despite this agreement, the Council of Agriculture Ministers – in apparent disagreement with the European Parliament – later allowed products containing up to 0.9 % of “adventitious or technically unavoidable” GMO content. In doing so, it argued that certification in organic farming mainly focuses on the production process, not on the end product. The result of this policy was that currently, each national organic certifying body applies its own standards, but in general, production is decertified in Europe if any organic product is found to be contaminated with GMOs above the set detection level (Verrière 2015).

Historical Background, Definitions, and Approaches to Coexistence

One perspective on the European approach to coexistence is that it aimed to open up for the definitive end of the *de facto moratorium* by supporting “the ability of farmers to make a practical choice between the conventional, organic and GM-crop production” (European Commission 2003a). As Franz Fischler, the European Commissioner of Agriculture, Rural Development, and Fisheries at that time stated in a speech about coexistence: “no form of agriculture, GMO or non-GMO, should be excluded in the EU” (European Commission 2003b). In fact, the concept was introduced during a period in which the United States, Canada, and Argentina had challenged the European Union over its *de facto moratorium*, arguing that it was an illegal ban without scientific foundation. This meant that the EU was under significant international pressure to open up for permitting GM crop cultivation. At the same, it was under significant local pressure to protect existing conventional and organic models of agriculture. The concept

of coexistence therefore emerged in this context as a kind of compromise of “good intentions” in which the interests of all aimed to be simultaneously met without explicitly recognizing the actual incompatibilities between the different models and social practices. However, allowing freedom of choice for economic operators, farmers, and consumers concerning GM and non-GM products is only possible with a functioning traceability and labeling system. This means that the ethical commitment to “freedom of choice” taken by European authorities required traceability and labeling laws to come into being together with recommendations and guidelines for coexistence.

In order to implement the idea of coexistence between agricultural forms and crop types, the European Commission issued nonbinding recommendations on measures to be developed and put into practice by the Member States, following the subsidiarity principle. The focus of these recommendations was on practices to be implemented at the farm level. In these recommendations, a clear and significant distinction was made between the economic aspects of coexistence and the environmental and health aspects. This division reinforced a strict – but also contested – demarcation between risk assessment and risk management by separating aspects to be evaluated by experts (e.g., aspects concerning environmental, human, and animal health assessed by the European Food Safety Authority under Directive 2001/18/EC) and those relating to policy (e.g., including social or ethical dimensions). This saw the coexistence issue reduced to the quantification of potential economic losses from admixture and an individual monetary compensatory mechanism for the costs derived from the market-driven differentiation (and labeling) between GM and non-GM products. By issuing “science-based” technical measures to deal with coexistence, the European Commission strategy also implied that the political debate could be “technified.” Therefore, the political efforts towards coexistence were effectively devoted to designing technical measures to minimize the costs caused by the implementation of the labeling directive (which was at that time under preparation and approved in September 2003) “in a

proportionate manner” so as to let the market operate “freely.” Liability was also exclusively focused on the economic aspects of coexistence. A trend towards individualization of the liability and redress scheme has been also promoted by the coexistence framework regarding the resolution of disputes in the European guidelines (Binimelis 2008).

These technical recommendations included: ensuring separation distances between GM and non-GM crops, thoroughly cleaning all agricultural machinery and transport vehicles, establishing independent drying and storage facilities for GM and non-GM crops, and avoiding similar dates of sowing between GM and non-GM crops, among others. Through the recommendation of these technical measures to ensure the separation of GM and non-GM crops, seeds and pollen, wider social debate on the acceptability, justifiability, or necessity of GMOs was reduced to a question of farmer’s individual choices, as if farmers acted independently from each other, from their networks of social relations, and from their own socio-economic and socioecological contexts. Additional nonmarket based socioeconomic issues that are more difficult to quantify or incommensurable, such as the loss of trust among consumers or the consequences of the admixture of GMOs for a local variety, were never considered.

As a result, and despite the establishment of this framework for coexistence, the social controversy surrounding GMOs in Europe continued, and many Member State governments continued their opposition to new GMOs approvals (e.g., through the use of the so-called safeguard clause of Directive 2001/18) while an increasing number of regions declared themselves to be “GMO-free zones”. This situation of ongoing resistance and dissatisfaction led the European Commission to adopt a more flexible approach in 2010 (European Commission 2010), issuing new guidelines for the development of national coexistence measures. These guidelines allowed Member States more freedom in the design of their coexistence measures to take into greater consideration specific regional characteristics. For instance, it was acknowledged that many organic and conventional operators in the food sector were using a 0.1 % threshold instead of the set level of 0.9 %, which could create income loss for

producers wanting to market their products as not stemming from GMOs or being GMO-free. The emphasis on “science-based” measures was also softened in the new guidelines. Importantly, the guidelines also opened the possibility to recognize GMO-free zones, which in fact challenged the foundational idea that GM crops could coexist alongside other forms of agriculture and placed enhanced idea on the importance of allowing for societal rather than individual choice over the agricultural system to be practiced.

Although these new guidelines allowed for a greater flexibility among the measures adopted by nation states, the authorization process for GMOs remained the same. This failed to account for the genuine challenges that implementing effective coexistence measures posed in practice and to address the ongoing questions concerning their ability to successfully control admixture as cases of contamination continued to mount. In 2015, a new Directive acknowledged some of these issues by allowing Member States to “opt-out” of the scope of a GMO cultivation authorization due, for example, to the *“high cost, impracticability or impossibility of implementing coexistence measures due to specific geographical conditions (...), or the need to avoid GMO presence in other products”* (Directive (EU) 2015/412).

Sources of Contamination

Agriculture is an open system. This makes the possibility of admixture between GM and non-GM crops to a certain extent unavoidable (Devos et al. 2009). Formally documented cases of contamination since 1997 are recorded in the online worldwide GM contamination register (see <http://www.gmcontaminationregister.org>), maintained by GeneWatch UK and Greenpeace. By the end of 2015, 434 incidents were recorded on this register (including various cases with unauthorized GM lines) although of course additional cases may occur but not be documented or reported. The registered cases of contamination show that the routes for admixture are often unclear. This is arguably because adventitious mixture or presence (meaning unintentional con

tamination with GM material) is possible at virtually all the different stages of the production chain. The most critical sources for this include (Marvier and Van Acker 2005):

1. The purchase and use of impure seeds (i.e., seeds that contain GM material)
2. Cross-fertilization of GM and non-GM crops due to pollen flow between neighboring fields
3. The occurrence of “volunteer” plants regenerating from seeds and/or vegetable plant parts from GM crops planted in previous seasons
4. A mixture of plant material from different crops in agricultural machinery during sowing, harvest, and/or postharvest operations (including the storage and transport systems)
5. Admixture during food and feed processing (including transport during these operations)
6. To a lesser extent, cross fertilization from certain sexually compatible wild or weedy relatives and/or feral plants

Policies in the Different Geographical Contexts (Europe Versus Other Countries/Regions)

Following the evolution of the positions of the European Commission and its Member States on the issue of coexistence, a variety of implementation strategies have been developed. While some countries have not adopted specific coexistence legislation (e.g., Croatia, Cyprus, Ireland, The Netherlands, Spain, or United Kingdom), other countries have adopted coexistence measures at the national (e.g., Czech Republic or Portugal) or regional level (Austria, Italy, or Finland) or issued a ban that is sometimes implemented along coexistence measures, which is the case of Germany. Furthermore, after the implementation of the aforementioned new EU Directive on GMOs (Directive [EU] 2015/412) in March 2015, 19 out of 28 countries also chose to opt out of cultivating the only currently approved GM event in Europe – maize MON 810 – in either all or part of their territories. The case of Spain is especially interesting here since it is the only European

country currently growing a GM crop (MON810 Bt maize) at a commercial scale and still does not have a coexistence framework. Without a coexistence framework requiring the implementation of any measures to effectively avoid contamination, organic maize production has practically disappeared from areas in Spain with GM maize cultivation (Binimelis 2008).

In recent years, the need to develop guidelines and measures to allow for coexistence has also spread to other non-European countries, including countries leading the production of GMOs, such as the United States, Canada, and Brazil. As mentioned above, in Europe, the focus is mainly on the economic losses suffered by farmers in which the value of their crops is reduced by the unintended presence of GMOs. In the United States and Canada, coexistence practices – which are also mainly focused at the farm level – are not based on regulations or policy guidelines but rather on market arrangements and, in some cases, guidelines for coexistence practices are produced by the sector itself (Rizov and Rodríguez-Cerezo 2014). In these countries, the unintended presence of GMOs has often led to the filing of a class-action lawsuit due to allegations of losses linked to trade disruptions. Examples of such situations include the cases around Starlink, Libertylink, Oregon soft wheat, or the Viptera corn. In fact, these class actions have been characterized as “*the front-line in a form of legal trench-warfare between opponents and proponents of GM crops*” (Phillipson 2015). In the case of Brazil, the National Technical Commission on Biosafety established minimum distances between commercial cultivation of GM and non-GM maize that were incorporated in a resolution (Resolution No. 4 of August 16, 2007) and published a guide for the practical implementation of technical segregation measures in maize.

Conclusions: To What Extent Is Coexistence Possible?

The principle of coexistence aims to ensure that farmers are able to freely grow the crops and pursue the agricultural system that they

choose – be it genetically engineered (GE), non-GE conventional, or organic. The idea of creating a framework for coexistence between crop types was introduced in 2002 in the European Union in order to facilitate the perceived right of farmers to choose and to respond to concerns regarding the admixture of GM with non-GM crops (organic or conventional). The framework developed involved establishing recommendations on technical measures to try and keep crops separated and reduced the significance of the issue to questions concerning monetary aspects for individuals. However, the issue remains unsettled and controversial, as both the foundations of the concept of coexistence and the specific measures to be applied have been highly contested for their applicability, comprehensiveness, and effectiveness. Indeed, coexistence itself has become a contentious notion, which although seeking to present a compromise position, in which the interests of various social actors are taken care of, fails to resolve previous conflicts related to the divergent political visions for the future of agriculture and the role that GMOs have to play in it. It also arguably creates new problems by both transforming a social debate into solely a matter of individual choice and also by individualizing its impacts, thereby weakening, isolating, and often dismissing the most vulnerable actants present in the agri-food networks involved (Binimelis 2008; Levidow and Boschert 2008).

Introduction

Cooperatives are formal social movements utilized around the globe often in reaction to various social-economic injustices and/or market failures. Their formation in the USA has been influenced by a legacy inherited from farmers and agricultural cooperatives developed first in Germany, Switzerland, Denmark, Ireland, and Iceland and from labor and consumer cooperatives in the UK, France, Sweden, Finland, Norway, and Italy. Historically disadvantaged farmers and/or workers have spearheaded their development both in Europe and the USA. They have also been used in a formal development context throughout the

developing world, often driven with a similar impetus to address social justice issues, though with mixed results. This entry focuses on agricultural cooperatives in the USA only, though the tensions specified here highlight the kinds of challenges and trade-offs faced by cooperatives elsewhere.

Agricultural Cooperatives in the USA

Agricultural cooperatives began to appear in the USA in significant numbers in the 1800s, though organizing efforts existed back into the colonial era. The period from 1890 to 1920 was particularly active, with as many as 14,000 farmer cooperatives operating by 1920. Much of this activity was triggered by a severely depressed farm economy of the 1890s, as well as the emergence of large corporate bodies that could exercise monopoly (seller) and monopsony (buyer) power over farmers. Cooperatives were organized to accommodate to the severity of economic conditions and to help empower farmers relative to the market power of much larger firms.

Cooperatives were controversial however in that they raised questions concerning collusion among farmers, price fixing, and violations of antitrust legislation. Hard fought political action prevailed in favor of farmers in 1922 with passage of the Capper-Volstead Act. Capper-Volstead provided farmers the legal right to market their output collectively. Currently there are 2285 agricultural cooperatives in the USA with an overall gross business volume of \$213.5 billion (Ali et al. 2011). Historically, they have accounted for approximately one third market share of all agriculture marketings and one quarter of supply purchases. Radical declines in numbers have occurred over time, due to the industrialization of farm production, globalization of competition, and organizational consolidations through mergers and acquisitions, as well as bankruptcies.

Most of the scholarly literature on agricultural cooperatives exists within two academic disciplines, agricultural economics, and rural sociology; and of these two, agricultural economics predominates by sheer volume of work. The

agricultural economics lens tends to resolve within a neoclassical perspective, with much of the writing (though not all) conflating to questions of efficiency, with important subtopics of study on finance, market concentration, market structure, life cycle of firms, value-added, and new generation cooperatives among others. Sociological research tends to resolve to issues of power, democracy, and social justice as viewed within three conceptual lenses, i.e., micro, mezzo, and macro. Microlevel research focuses on social-psychological and demographic determinants of participation. Participation is understood both as economic patronage and involvement in democratic governance. The mezzo level of analysis examines the design of organizations to achieve such governance provisions as member oversight, policy making, as well as participation. Macro levels have focused on such issues as women's involvement in decision-making, market concentration, conversion of cooperatives to investment firms, choice of cooperative structure, impacts of technological change on cooperatives, and cooperative functions in alternative food systems. Both economic and sociologically relevant literature can be found in the *Journal of Cooperatives* and its predecessor the *Journal of Agricultural Cooperation*, *Rural Sociology*, *Sociologia Ruralis*; *Journal of Rural Cooperation*, *Journal of Cooperative Studies*; *Journal of Agriculture, Food Systems, and Community Development*; *Annals of Public and Cooperative Economics*, *Agribusiness*; and the *American Journal of Agricultural Economics*. There are significant libraries online at the University of Wisconsin Center for Cooperatives, the Center for Cooperative Studies at the University of Saskatchewan, and the USDA, Rural Development-Cooperative Programs web page.

Much of this literature is unidimensional, however, in the sense that it does not present cooperatives' intrinsic design and history as full of opposing tensions and contradictions. It tends to be strictly economic or sociological without a more holistic detailing of various trade-offs and dilemmas. In introducing agricultural cooperatives for this entry, their organizing principles as designed to be distinct from investment-oriented

firms (IOFs) will be reviewed, as well as their traditional role as providing countervailing power for farmers, and as conditioned by the development of integrated "dirt to plate" value chains since the turn of the last century. These aspects of cooperatives, i.e., their design and role, themselves generate additional tensions internally within the organization and externally in relation to a dynamic socioeconomic and highly competitive environment. Mooney (2004) and Gray et al. (2001) have specified several of these tensions and dilemmas in various publications; to include complex expertise/grass roots needs, efficiency/equality, bureaucracy/participation, and authoritarian logic/democratic logic. Three iconic tensions will be highlighted here, (1) capitalism/democracy, (2) local/global, and (3) production/consumption. Examination of these tensions will be used to highlight how cooperative institutionalization (i.e., diminution of original democratic commitments, embeddedness and power) has occurred over time, but also how, as organizations, they continue to hold promise for addressing larger contextual challenges.

Organizational Design and Cooperative Difference

Cooperative Principles

Cooperatives are organized around a set of guiding principles, variously formulated and presented by the International Cooperative Alliance (2013) and as referenced in Zeulie and Cropp (2004) among others. These principles were first formally codified by the Rochdale weavers of England in the mid-1800s and Schulze and Delitzsch of the German credit union movement during the same period.

Central to all formulations is an emphasis on member/owner/patron **use** of the activity of the organization. "Use" can involve, among many functions, assembling of a commodity, grading, processing and manufacturing, and wholesaling and retailing. Products might include, among others, milk, fruits and vegetable, grains, livestock meat, as well as supply purchases. This use aspect of cooperatives is perhaps best

captured by Dunn (1988) in three cooperative principles as:

1. The user-owner principle: Those who own and finance the cooperative are those who use the cooperative.
2. The user-control principle: Those who control the cooperative are those who use the cooperative.
3. The user-benefits principle: The cooperative's sole purpose is to provide and distribute benefits to its users on the basis of their use.

While other versions exist, this set of principles best highlights the use aspects of cooperatives. Designed for use is perhaps one of the most distinctive features of cooperatives, particularly when compared to their organizational rivals, investment firms. The following section provides greater detail on cooperative to IOF differences, in order to emphasize what they are, by also reviewing what they are not.

IOFs and Cooperatives Differences

Investment-Oriented Firms: In linear logic, investors with money seek to make a return on their money by investing in an activity that will return a profit, thereby ending up with more money. Investors-owners have little connection to the business activity of the firm. If use is made of the activity, it is only on an incidental basis. Governance is, in part, organized by shares owned. Typically shareholders have one vote per share held, i.e., votes are tied to shares owned. They are no organizational limits on the amount of shares any one investor can own. Since votes are attached to shares, this allows for concentrations of influence and power in ownership. These concentrations are not discouraged since it is understood that those with the most ownership capital have the most at risk.

A board of directors, elected by the shareholders, provides policy making and strategic planning, as well as long-term oversight and direction of the firm. A Corporate Executive Officer (CEO) is hired by the directorship to assemble a complement management team to handle the daily decision-making and activities of the firm.

It is not unusual for the firm CEO to be a major stockholder of the firm, also permitting additional concentrations of power in cross board/management relations. These concentrations are encouraged, since managers with ownership are seen as increasingly vetted to firm success. Firm success ultimately translates as profits. The fundamental and organizing logic of the firm, as with all investment firms, the dominant business form globally, is to make a return on investment (roi) for its shareholders.

Cooperatives are distinct from IOFs in use, ownership, and governance. In a cooperative, members (or potential members) of a cooperative may need a service or a product and collectively organize in order to provide it or obtain it at a more reasonable price. The organization must achieve some financial margin over costs, to continue to finance, and provide for a flow of services through time. They are not organized to make a return on investment. For cooperative patrons, the activity of the organization (and their use of that activity) is central to their relationship with the firm. Ownership is based on use rather than on shares purchased. Members own the cooperative in proportion to the use they make of it. The more they use the organization, the larger their contribution to its funding and ownership, as well as the greater the benefits received. Generally, no matter how much each member owns, they still have only one vote in elections, i.e., one-member, one-vote, though proportional voting is utilized in a small percentage of cooperatives. In proportional voting, the more a member uses the cooperative, the greater the volume accounted for by their patronage, the more votes held. However, the predominant voting/governance system used in the cooperative community generally is based on one-member, one-vote. Members elect a governing board either directly or through an elected delegate system. The elected board provides policy making, strategic planning, long-term oversight, and direction of the firm. A Cooperative Executive Officer (CEO) is hired by the board to assemble a complement management team and to handle daily decision-making and activities of the firm. In a cooperative, while the CEO may also be a farmer and a member,

farmer-member status does not entitle a manager voting rights any different from any other farmer-member.

For cooperative patrons, the activity of the organization (and their use of that activity) is central to their relationship with the organization. Ownership, governance, and use of the activity are contained within the same group of people in an internal relationship of membership; the fundamental and organizing logic being to provide service (broadly defined) through time to members. The multiple functions of cooperatives as patronage (use), ownership, democratic governance, and equality are organizationally designed for and emphasized.

Traditional Role as Countervailing Power

Cooperatives are often formed when “overproduction” results in low prices (relative to costs) and/or when “holdup” situations occur, such that a monopsonist (single buyer) or a oligopsonist (few buyers with a large market share) can dictate prices to independent producers. By aggregating, farmers are able to coordinate sales, gain some market power, and improve incomes. Similar dynamics can occur upstream when purchasing from a single seller (monopoly) or oligopolist (few sellers with large market share). By organizing, members can assemble their own input-supply orders and services without having to rely upon monopoly and/or oligopoly firms. Agricultural cooperatives have integrated into value chains as well, processing their output, giving themselves scale and product niche for capturing value, rather than turning their output over to commodity traders and private processors.

Modification of Countervailing Role

Beginning with the emergence of what some have termed “the new agriculture” (Boehlje and Schrader 1998; Gray 2000) at the turn of the last century, various technological developments, e.g., information monitoring and biotechnology, have permitted very tight vertical integrations of food chains from “dirt to plate” in some sectors of the agricultural economy. Large agribusiness multinationals, e.g., ConAgra, Cargill, and ADM,

developed these chains, while holding large market shares across several commodities. These chains are solidified with contracts between firm and farmer, such that the firm controls many of the production decisions, while limiting farmer control over their own output. Where production contracts are used, farmer empowerment is often diminished.

Cooperatives are caught by the limits of their own structure. Large IOFs can offer a diversity of products, produced in different locations, with set limits on amounts of product accepted from farmers. They can control their supply. Cooperatives, as vehicles for their farmer-member-owners, are obligated to accept, with some few exceptions, the entire product their members bring for marketing/processing. They guarantee a market, no matter how much product members seek to market. Farmers are embedded in location, by the location of their farms, and as such cooperatives are embedded locationally by of their membership. Farmer-owner-members generally are committed not only to the activity of farming but to specific products of production. These aspects of quantity, location, and product represent rigidity relative to large IOF multinationals with their multiple locations, multiple products, and the capacity to limit acceptance of product from suppliers.

Continuing technological developments, firm flexibility, and access to resources facilitate IOF development of a diversity of differentiated products, and segmented markets that are integral to the formation of tightly controlled value chains. This presence as a market force allows IOFs to forgo price competition (a possible cooperative leverage) in favor of competing with brands, advertising campaigns, research and development, and expansion in plant capacities (Gray et al. 2001).

Under these conditions gaining market access for farmers can become a problem, let alone being able to countervail IOF power. The strategy taken by some cooperatives, e.g., Land O’Lakes, Cenex-Harvest States, Profac, has been to partner and to form joint ventures and strategic alliances with IOFs. IOFs can integrate into IOF-owned value chains, the core competencies of

cooperatives, i.e., the ability to handle massive quantities of primary commodities in a regulated and predictable fashion, with direct links with farmers. Farmers in return obtain access to markets for their products.

However, when these cooperative to IOF relationships occur, they do mix organizational logics and tend to place “use” in a subordinate position relative to “roi” and the profit interests of stockholders. Very few if any agricultural cooperatives can approach the scope and market presence of such deep pocket firms as Cargill, ADM, ConAgra, or Dean Foods. Possibly Cenex-Harvest States, Land O’Lakes, Dairy Farmers of America (DFA), Ocean Spray, some of the largest agricultural cooperatives in the USA, are positioned in terms of scale and scope to challenge IOFs in the interests of their farmer-members. However and paradoxically, to the extent cooperatives take this path, they also put various democratic-member responsive aspects of the organization at risk.

Socioeconomic Tensions

Cooperatives must operate with the multiple functions of farmer use (governance, ownership, benefits,) with organizational commitments to equality and democracy, in a context primarily dominated by investment firms and IOF logic. These relationships among members, cooperative firms, and competitive context can act as tipping points to the character of the cooperative organization. Consideration of these tensions and shifts integral to them can help explain cooperative institutionalization (i.e., loss of democratic commitments and embeddedness, as well as loss of power) though it can also highlight some of the continued promise of cooperatives.

Democracy/Capitalism

While cooperatives are democratic organizations of members that emphasize use, they must also realize earnings to survive over time. They must function as a democracy in a context that emphasizes share, roi capitalism. The cooperative-democracy/capitalism tension is perhaps better

understood with some greater detail as “person-use-democratic-organization/capital-return on investment (roi)-share-organization.” Cooperatives privilege personhood, IOFs privilege capital. Cooperatives privilege person-use, IOFs privilege capital-return on investment; and cooperatives privilege democracy and equality, IOFs privilege share-voting and proportional governance.

Earnings must be made in competition with a predominant business form that emphasizes short-term return on investment. IOFs as the dominant business form in the larger sociopolitical economy create a context of pressure that pulls on cooperatives to adapt to the needs of capital rather than the needs in use. Needs of capital are often translated as the need to be unencumbered for efficiency reasons and due to a return equivalent to the size of investment – argued as “investment will not occur otherwise.” The tension, “person-use-democratic-organization/capital-return on investment (roi)-share-organization,” becomes very real with considerable pressure from within the competitive context, to simplify it toward a “capital-roi-organization.” From a neoclassical economics perspective, to do otherwise is not to be efficient.

There are then, frequent threats to the “one-person, one vote” principle in terms of modifying it, eliminating it, or de-vitalizing it due to the unintended consequences of other dynamics. Direct threats can often come out of the theoretical agency of neoclassical economics. From this position, arguments are made to shift one-member, one-vote to proportional voting, i.e., aligning votes held to volume transacted with the cooperative. It is a general practice in cooperatives that as “use” is made of the cooperative, equity contributions are assessed according to “use” made of the organization. The greater the volume transacted by a member, the more equity, and in proportional voting, the more votes. However, when proportional voting is used, it de-privileges equality of member and personhood and in turn weights organizational rationality toward the needs of capital, and in particular toward the selective needs of larger farmers. Larger farms, in general, account for greater level of volume committed. With proportional voting, equality fades.

At other times there is pressure for the wholesale restructuring of cooperatives to IOFs (e.g., California Olive Growers, Calavao Avocados, GoldKist, Capital Milk, American Rice, Saskatchewan, Manitoba, and Alberta Wheat Pools). Conversion to IOFs simplifies cooperatives away from the multiple values of “use” and the potentialities of democratic voice and reorganizes them to a singular logic of roi and exchange value. Conversion eliminates the democracy/capitalism tension entirely and shifts the organization to a capital-roi rationality.

There are secondary pressures that serve to devitalize democratic principles. As mentioned previously, there has been considerable concentration of ag-markets such that large agribusiness IOFs often hold commanding market shares (e.g., Cargill, ADM, and ConAgra). These firms set the competitive context for cooperatives in many sectors. To accommodate to this competition (as well as to the decline in farm numbers due to farm industrialization), many cooperatives have merged, made acquisitions, and formed joint ventures creating complex bureaucracies in their own right. These structures create distance between farmers and the decision-making points of the organization, thereby muting democratic dynamics, even if one-person, one-vote principles are followed (Fairbarin 2004). These distances are even more elongated, and in fact there can be a near complete fracture of member voice in cooperative/IOF joint ventures. Boards of directors continue to be elected from farmers, though the complexity of these organizations and expertise required to function on boards can be well beyond the skills of individual farmer-members.

This distance is complicated by a management that frequently holds more information about, for example, law, finance, and marketing than directors. Fulton and Larson (2012) refer to this dynamic as a problem in “asymmetry of information” between agents and principal, agents being a management, hired by directors, and directors acting as the principals of the organization (ultimately serving at the behest of the members). Fulton and Larson (2012) suggest the agent/principal problem is more complicated by CEOs who come with different agendas, often based in

inflating their own marketability and exchange value in the larger national and global market. They tend to conceive and manage organizations in a manner congruent with the management of IOFs. Their performance expectations may be based in “grand visions” for the organization and such personal goals as high salaries, perks, and job security (Sousa and Herman 2012). Under these circumstances the board may come to be in a near dependent relationship to management, rather than in a position as strategic decision-maker.

To continue through time in providing service to members organized around use values, the cooperatives must retain the use/financial returns tension. Earnings are necessary to maintain the financial needs of the organization. However, vigilance must be exercised to prevent a dominant tipping toward roi imperatives (in spite of the considerable pressures to do so, as articulated above). To do otherwise is to render impotent the use-democracy aspects of the organization (Gray and Stofferahn 2014).

Local/Global Tension

In pursuing growth and profitability, some cooperatives have developed global locations (e.g., Cenex-Harvest, Land O’Lakes) to compete with investor-oriented transnational corporations (TNCs). This adds another layer of distance (i.e., physical distance) between members, member governance, and cooperative decision-making. This distance can then tip a member/management tension toward management prerogatives (the agent) as well as the needs of capital.

Globalization, along with bureaucratization, tends to demand standardization and often a resulting subordination of unique local qualities. Cooperatives, given their unique user-owner character, have a strong tendency to be locally embedded. Equity-capital resides with the user-owners and in the case of farming, where user-owners live, i.e., on the farm. This is quite different from investment-oriented capital that seeks fluidity and freedom (as opposed to freedom of the person). Local embeddedness from the standpoint of capital and from the agency of neoclassical economics is an unnecessary constraint that interferes with

mobility and the efficient application of capital resources. However, from a person-centered understanding, geographic embeddedness prevents capital flight. Mooney (2004, p. 88) suggests that, from a historical perspective, “geographic embeddedness serves a long-term functional adaptation (an efficiency of a different sort) that shields cooperatives and communities to which they are [embedded] from . . . recession that would drive capital from the region.”

While cooperative character results in a natural embeddedness, the demands of a neoclassical efficiency and the mobility of capital, IOF competition, organizational complexity, globalization, and CEO managerial culture, call for a “freeing-up” and disencumbering of capital from locally “constrained” attachments. Like the person-use/capital-investment tension, cooperatives need some degree of both in terms of market development, but an overemphasis can result in a loss of local identity as well as a differentiated uniqueness that only embeddedness can provide (Gray and Stofferahn 2014).

Production/Consumption Tension

There is little acknowledgment in either the cooperative literature or in cooperative practice, of the importance of deliberately linking production with consumption. However, it is of central importance in the context of challenges from the larger sociopolitical economy; and it is here that agriculture cooperatives hold the most promise. The current organization of agriculture tends to treat various environmental and human costs as externalities. There is little opportunity, beyond direct government regulation, to bring these costs inside business decision-making, particularly as organized around IOF logic and rationality. This is in part due to the severe market separation of production and consumption. Production and consumption interests tend to be understood at antagonistic poles. Yet they presuppose each other, one requires the other. Production anticipates consumption, consumption anticipates production.

As a potentiality and as articulated from an earlier tradition of cooperative development, Voorhis (1961, p. 150) suggests the development of a cooperative commonwealth: “. . .if a

considerable proportion of farm crops [and food] could be sold directly by farmer-owned enterprises to consumer-owned ones, the spread between what farmers receive and what consumers pay would amount simply to the costs of processing, transportation and sale” (as cited in Mooney 2004, p. 85). This would raise the possibility of better returns to farmers and lower prices to consumer. Perhaps more importantly, “member-users” of the respective services of agricultural and consumer cooperatives could provide, through democratic process (and through the use values of governance, ownership, and benefits) a basis for internalizing what has been externalized (Mooney 2004). Health, environmental, and land-use concerns would no longer need to be as external as they are with the roi logic of investment firms. With membership and use values of democratic governance and ownership, what exists in a member’s life world (e.g., environmental and social costs among many other things) could be internalized.

The potential of cooperative organizations to internalize externalities with use values, and through their respective democratic process, provides a potentiality for addressing these problems. In a relative sense, this potential is much greater than the singular rationality inherent in IOFs, given their characteristic external and disconnected relations among production, investment, ownership, benefit, and consumption. The emergence of community-supported agriculture (CSAs), farm to school and institutional agriculture, farmers’ markets, cooperative farm stores, and produce auctions, though yet on an incipient level, demonstrates the viability of this linking (Gray 2005). Many of these initiatives are organized either formally or informally along the guidelines of cooperative principles (Gray and Stofferahn 2014).

Summary

Agricultural cooperatives’ distinct form and role in countervailing investment-oriented firms in the marketplace has generated a series of socioeconomic tensions, both internally and in relation to the external environment. Three iconic tensions addressed here were democracy/capitalism, local/

global, and production/consumption. To varying degrees, both aspects of these tensions are needed to preserve cooperative character. While cooperatives are democratic organizations of members that emphasize use, earnings must be realized to continue to provide use value over time. However, an overemphasis on earnings can result in loss of its democratic voice aspects. Cooperatives need both local embeddedness plus some degree of geographic expansiveness for market development; however, an overemphasis in expansion can result in a loss of local identity, product uniqueness, as well as member voice. Historically it has been difficult to retain the tensions in a balance that preserves cooperative democratic character. Various technological and industrial developments, organizational consolidations, as well as the globalization of IOF competition have shifted firm shape and behaviors toward an investment model and away from the local and toward the global.

LeHeron and Roche (1997) suggest more energy be spent from a civic legacy perspective, on sorting out and bequeathing institutions to future generations that are structured for democratic voice opportunities. As economic entities, agricultural cooperatives may be among one of the few institutions in rural areas that retain a semblance of democratic governance (Mooney 2004). Those cooperatives, in intense struggles with large multinational corporations, have surely lost some democratic vitality as discussed above; though from a comparative perspective, they continue to account for greater local ownership than IOFs.

Both Alperovitz (2013) and Wolf (2012) highlight cooperatives as a possible alternative solution to the current systemic problems of economic stagnation, unemployment, and environmental degradation. Alperovitz in particular, speaks of alternative forms of ownership, cooperatives, and credit unions, among others, as representing a possible “prehistory.” He posits that while some alternative forms of ownership and production may be in a weak or early stage of development, they may gain much greater ascendancy if the objective conditions of everyday living continue to worsen. The current incipient but rapidly

growing nature of community-supported agriculture, farm to school and farm to institution agriculture, farmers’ markets, and cooperative farm stores may be a methodology that brings production and consumption together in a more collaborative way and in a manner that currently is oftentimes facilitated with the democratic voice opportunities of cooperatives. By internalizing into an organization with democratic voice and use opportunities, i.e., governance, ownership, and benefits, various environmental social and economic costs might be more holistically addressed (The views expressed in this entry are those of the author and do not necessarily reflect those of any associated program, department, administration, or university (Gray and Stofferahn 2014)).

Agricultural Ethics

[Farming ethics](#)

Introduction

Agricultural ethics is a form of practical ethics that addresses ethical issues or questions that arise in conjunction with the production and distribution of food and fiber goods. The scope of agricultural ethics is, in one sense, delimited by the scope of agriculture. Conceived narrowly, agriculture is the use of technology to cultivate crops or the practice of animal husbandry: A narrow scope would exclude the various forms of scavenging, hunting, or fishing that have contributed to human food needs for centuries. It might also exclude activities that occur after food crops or animals leave the premises of a farming operation, including transport, milling or slaughter, further processing, food manufacturing, food or fiber distribution, and retail sales. Defined more broadly, the scope of agriculture might include all of these activities and might further be extended to include a variety of natural resource management practices such as forestry, game management, and water resource conservation. An even broader definition might follow from the scope of research institutions and government ministries organized around the idea of agriculture, which might include all of food safety, veterinary medicine, parks and tourism, or any of the applied biological science activities that support these more practical activities. In its broadest definition, agricultural ethics would thus encompass all the subject matter contained in the *Encyclopedia of Food and Agricultural Ethics*, though common parlance would probably deploy an implied distinction between agriculture and cooking, on the one hand, or dietetics and nutrition, on the other.

Given that many if not most of the other articles in this volume are dedicated to substantive topics falling under the general heading of agricultural ethics, this article will make no further attempt to survey, list, or categorize the topics that would be included under the heading of agricultural ethics. A quick look at the *Encyclopedia* index will provide an overview. However, there are a number of philosophical and methodological questions that arise in connection with the content and approach in agricultural ethics: Is agricultural ethics best thought of as an application of more general ethical theories? Does a non-theory-driven approach to practice speak to ethical issues in agriculture? Is there anything unique or special (other than general subject matter) that would distinguish agricultural ethics from other forms of practical ethics, including business ethics, medical ethics, environmental ethics, journalistic ethics, or research ethics? What is the relationship between agricultural ethics and these other fields, and especially environmental ethics, given the latter's concern for environmental impacts of human practice and the ethical norms that should apply to our treatment of nonhumans, including animals, species, and ecosystems? How does agricultural ethics intersect with classical approaches in philosophical ethics such as consequentialism, deontology, or virtue ethics? What is the relationship between agricultural ethics and the broader tradition of philosophical inquiry and writing? The balance of this essay will take up each of these questions in turn.

Agricultural Ethics and Ethical Theory

Many philosophical problems within agricultural ethics are, in fact, typical of practical ethics in general. Practical ethics is the division of ethics in which arguments or analyses are expected to bear directly on human practice or action. An inquiry in practical ethics addresses the general question "How should we act?" in reference to specific circumstances faced by individuals or groups. Practical ethics can be distinguished from *metaethics*, where the focus of the inquiry is to provide a general account of the nature and

logic of ethical conduct or decision making, and from *ethical theory* where the focus is to articulate a broadly – often universally – applicable theory of right conduct. Some theorists in practical ethics (including agricultural ethics) presume that arguments addressed toward steering or evaluating human conduct in specific cases should *apply* ethical theories. For them, the task of practical ethics is to specify empirical details that would make general norms or principles supported by ethical theory (e.g., act so as to produce the greatest good for the greatest number) meaningful and action guiding in a particular situation. Hence, some theorists characterize agricultural ethics as a form of *applied ethics*. Other theorists have questioned this model and see practical ethics as a process of moral reasoning in which individuals and groups indeed bring judgment to bear on human conduct, but not in a manner that can be accurately described as the application of a moral theory. Thus, for example, one might think of ethical theory as a way to generate arguments and systematize reasoning so that many different possible reasons could be considered at the moment of evaluation or practical decision making, rather than as an activity prior to practical decision making where general principals of moral correctness are adjudicated.

Some authors writing in agricultural ethics seem clearly to explore the implications of a particular theoretical approach for problems that arise in the production and distribution of food and fiber. The most prominent example in contemporary times may be Peter Singer. Singer is widely known for work on two key problems in agricultural ethics, global hunger, and the treatment of livestock. In both cases, his practical conclusions derive from a general moral principle: If one can do something that alleviates great harm to one party at very small cost (or harm) to oneself, one is morally obligated to do it. Singer has argued on the one hand that this principle is so general that it would be endorsed by everyone, without regard to their commitments to a systematic and consistent view of morality (e.g., an ethical theory) (Singer 1972). On the other that the principle is strongly supported by a sophisticated version of utilitarianism, and Singer's book *Practical Ethics* makes

this connection explicit (Singer 1979a). Either argument can be seen as strategy for establishing a general principle that can then be applied to specific cases so as to generate action-guiding recommendations in practical ethics.

In the case of hunger, Singer's application of the principle has been to support arguments that comparatively better-off people (such as any middle-class person from an industrial economy) are morally obligated to divert some portion of their income to help hungry people. In early versions of this argument, Singer focused specifically on the obligation to support efforts at famine relief. He argued in favor of food aid, first and foremost as personal obligation that individuals would fulfill through donations to organizations (such as CARE or Oxfam) dedicated to the relief of hunger but also as a political obligation to support actions by governments that would also be organized around feeding hungry people. In later work, the argument was formulated more generally as an obligation to help people in extreme poverty, without specifying that the target of assistance is necessarily tied to relief from hunger and the delivery of food aid. Singer's modification of this argument may have reflected his growing awareness that food aid can have deleterious effects on poor farmers; hence, a prescription too narrowly focused on food may support forms of action that, in fact, *fail* to satisfy the terms of his general principle.

With respect to animals, Singer has argued that the suffering endured by livestock in modern production systems is very great in comparison to the pleasure that human beings derive from consuming meat and other animal products. Thus again in a fairly straightforward application of his general principle, Singer argues that individuals are obligated to desist from consumption of animal products that have been derived from conditions in which livestock suffer (Singer 1975). Singer has shown awareness that this position does not prescribe vegetarianism in all cases. Certainly in cases where consumption of meat, milk, or eggs is necessary for survival, eating animal products would be morally justified. More subtly, if animals can be raised under humane conditions and slaughtered painlessly, Singer's general principle

might not entail any form of vegetarianism. Humane dairy and egg production, for example, might be compatible with Singer's principle; hence, veganism would not strictly be implied. What is more, Singer has at one juncture argued that the painless death of a nonhuman animal is not a deeply significant form of harm to them; hence, there may be circumstances where eating meat would be justifiable, as well (Singer 1979b).

In both hunger and animal ethics, Singer's arguments reflect an approach that can be accurately characterized as an application of ethical theory to a specific problem in agricultural ethics. His approach to practical ethics is to first assert and argue for a principle or rule, then to explore the implications of that principle with respect to key issues arising in connection with agriculture and food. Singer's work is thus a particularly apt illustration of the applied approach, but others who see agricultural ethics as a form of applied ethics would reject his commitment to utilitarianism and consequentialism. Several philosophers who have written on the two problems of most interest to Singer – animal use and global hunger – exemplify the application of deontological or neo-Kantian ethical theory. Tom Regan's book *The Case for Animal Rights* was an explicit attempt to develop an approach to the ethics of animal use that draws on Immanuel Kant's philosophy. Regan argues that many nonhuman animals – including all livestock species – are “subjects of a life.” They exhibit the features that we associate with mentality or mental life. They are conscious and sentient – features noted by Singer in connection to their ability to feel pain – but they are more than simple receptacles or vessels that, like an empty glass, get filled up with painful or pleasurable sensations (Regan 1980).

Regan's work is more characteristic of an applied approach than Singer's in one important respect. Regan's strategy is to first refute ethical theories such as utilitarianism, arguing that they fail to show adequate respect for the individual dignity of beings that have sense of their own individual identity as subjects. Indeed, Regan finds fault with Kant's own theory, arguing that it fails to recognize animal subjectivity. Once other theoretical approaches have been shown to

be lacking, Regan offers his own theoretical alternative. In Regan's view, *any* relationship defined by instrumental use of a creature who possesses subjectivity fails to respect that creature's dignity. Theories that are not based on respect for subjects of a life are, given Regan's arguments, going to fail with respect to animals and also with respect to many human beings, including children and adults with severely compromised cognitive capacities. It is on these philosophical grounds that he finds animal production in general, and certainly any use that involves the death of the animal, to be strictly forbidden on moral grounds.

Philosophers including Onora O'Neill and Henry Shue developed deontological approaches to the question of global hunger. In *Faces of Hunger*, O'Neill argues that global hunger places human beings into positions of abject need, a position that is totally incompatible with Kant's master principle of ethics, the Categorical Imperative. It is impossible to will that people should occupy such positions of abject need and vulnerability as a universalizable principle of morality; hence, those social and political practices that create circumstances of hunger are inconsistent with the most basic demands of morality (O'Neill 1986). Shue developed a general theory of rights in his book *Basic Rights* such that basic needs of health and bodily integrity have priority over political rights such as freedom of speech, assembly, and the right to pursue economic endeavors in a market economy. A global order in which some are hungry violates the basic principles of a just society and cannot be rationalized on moral grounds (Shue 1980). Deontological arguments such as those developed by O'Neill and Shue have been generalized by philosophers working in development ethics, where the specific emphasis on hunger is often underplayed in favor of a more general discussion of poverty, deprivation, and subsistence needs.

Although the details of these arguments are worthy of attention in their own right, the point to stress in the present context is that Singer, Regan, O'Neill, and Shue can all be seen as following a philosophical approach in which key philosophical matters are decided on purely theoretical and abstract grounds. Subsequent to *this*

philosophical debate at the theoretical level, the concepts, rules, and reasoning characteristic of the given theoretical approach are then applied to a particular case. Animal use and hunger are considered to be cases to which the theoretical apparatus of a deontological or consequentialist theory can be applied, but cases do not bear on the question of which theory to adopt except in so far as the application of a theory suggests a result that is viewed as so profoundly curious and inappropriate as to be found absurd. The use of cases to refute or challenge applied results brings up the problem of intuitions in ethics.

Practical Ethics and the Problems of Agriculture

The applied strategy in ethics was sharply criticized by philosophers such as Alasdair MacIntyre and Bernard Williams, both of whom suggested that the moral significance of outcomes, the basis of rights, and the application of concepts such as dignity, virtue, character, and vice are better understood and utilized when one does *not* presume that they can be configured in terms of general theory of morality or moral decision making (MacIntyre 1984; Williams 1985). Broadly sketched, MacIntyre and Williams represent a tradition in ethics which presumes that moral concepts provide a basis for moral inquiry and moral discourse, for conversations, debates, and deliberations about what is right and what should be done. They hold that there is no general theory that explains how conversation, debate, and deliberation should determine ethical correctness for every conceivable circumstance. If that were the case, one could dispense with the conversation, the debate, and the deliberation and simply hand the problem over to an expert schooled in the details of moral theory. In contrast to those who develop detailed theories of ethics, this school of thought in practical ethics presumes that there is no substitute for actually engaging in an inquiry or moral discourse. They hold that one should not presume in advance some set of prior considerations about what kind of arguments or considerations will be deemed relevant to participants in a

moral discourse or inquiry. Furthermore, advocates of this approach would argue that *having* these conversations, debates, and deliberations is precisely what philosophers have always done. In contrast to an approach that stresses the application of theory, this approach stresses the process or procedure for conducting an ethical inquiry.

Anyone advancing a point of view on a topic of relevance to agriculture and the food system might take themselves to be participating in a conversation with others who can be expected to have contrary opinions. Any collaborative exchange of views that is dedicated toward improving judgment or understanding the basis for action fulfills the most basic procedural requirement for ethical inquiry. An argument that appeals to concepts and principles associated with prominent ethical theories (such as utilitarianism or deontology) can be advanced as a reason or rationale pertinent to a given topic without this also implying an overarching commitment to that theory or to the belief that ethical questions must ultimately be settled by arriving at a comprehensive and internally consistent theoretical outlook. One can assert that something should be done because it promotes the greatest good for the greatest number without also asserting that *every* ethical question can be settled by appeal to this utilitarian principle. Although a procedural approach is open to reasons that apply the familiar arguments of ethical theory, it does not presume that the philosophical debate among advocates of competing theories is particularly relevant to determining right action or conduct in a particular case.

Procedural approaches do require that argumentation be sincere. Participants in an ethical conversation, deliberation, or debate must be dedicated to actually getting the ethics right, as opposed to simply prevailing over other perspectives. This simple requirement has profound implications. Firstly, it presumes that the debate is truly open: There is a genuine question at stake as to what the outcome of an ethical deliberation should be. It also implies that participants in an ethical debate must take their own views to be fallible – potentially capable of being shown wrong, mistaken, or in some other way

inadequate. It implies that perspectives should be viewed as subject to revision in light of comment or critique by others. All of these characteristics distinguish a genuine ethical inquiry from frequently encountered real-world settings where people offer arguments primarily to create difficulty or trouble for enemies or antagonists who have different interests or political objectives. Although persuasion is an important component of ethical inquiry, the fundamental spirit of ethical inquiry is violated when persuasion is attempted by people who are not also willing to be persuaded.

There is thus a structure or system of practice that shapes ethical discourse. To the extent that this system can be characterized in terms of rules, it might be said to govern ethical discourse. Such rules could be said to form a basis on which ethical discourse could be distinguished from other forms of thinking, symbolic practice, or communicative exchange. Some philosophers have dedicated themselves toward a general description of this structure and to stipulation of basic rules. In the twentieth century, both John Rawls and Jürgen Habermas undertook this task. Habermas's "discourse ethics" can be understood as a theoretical project intended to place a general philosophical framework around constructive ethical disagreements, without also stipulating specific ethical principles that indicate the outcome of a debate in a particular case (Habermas 1990). Discourse ethics has been characterized as a form of ethical pragmatism by some authors writing in agricultural or environmental ethics (Thompson 2002; Norton 2005). However, philosophical debate over the nature or specifics of the rule structure for ethical discourse quickly becomes just another approach to ethical theory. What distinguishes *practical* application of discourse ethics in agricultural contexts is the practice of debating ethical issues directly, without prior development of an ethical theory whose tenets are being explicitly applied.

Procedural or discourse approaches are especially attractive in agricultural contexts because they encourage nonspecialists to participate directly in ethical debates. Anyone who is willing to offer reasons for a prescriptive claim

can do ethics. But nonspecialists may be more willing to participate if they are given a rubric for guiding them toward key ethical questions or topics. Tom Beauchamp and James Childress developed a rubric for initiating ethical discussions or debates in medical bioethics that features four key principles that can be discussed and evaluated with respect to any proposed activity: autonomy, beneficence, non-maleficence, and justice (Beauchamp and Childress 1979). Consideration of autonomy will direct discussants to consider how the activity encourages or possibly violates the freedom or agency of stakeholders. Discussion of beneficence involves a consideration of the benefits of the activity, while non-maleficence is a restatement of Hippocrates (c.460–379 BCE) master principle for physicians: First, do no harm. Justice is a principle that encourages participants in an ethical discourse to consider how the benefits and burdens of a biomedical activity or policy are distributed across various types of social groups (e.g., by income, gender, racial, ethnic, or other relevant social grouping).

Ben Mepham introduced a similar heuristic device in agricultural ethics which he called “the ethical matrix.” Mepham’s approach involved an $n \times n$ matrix in which principles much like autonomy and beneficence define one axis, while various types of agent or affected party defines the other (Mepham 2000) (► [“Ethical Matrix and Agriculture”](#)). This augments the discussion that might be generated by a Beauchamp and Childress rubric by directing discussants to consider how living human beings, unborn future generations, nonhuman animals, and finally entities such as species or ecosystems might be affected by an activity. The matrix thus is especially relevant for activities where it is important for an ethical discussion to consider environmental impacts of various kinds. Using the matrix approach does not necessarily imply that every cell defined by the grid will be ethically significant, only that discussants should at least ask themselves whether they might be. So, for example, a matrix with “autonomy,” “benefits and costs,” “social justice,” and “virtue” defining the rows and “living humans,” “future generations,”

“animals,” and “ecosystems” defining the columns will generate 16 cells. Discussants might conclude that there is nothing interesting to say about the intersection of “autonomy” and “ecosystems,” though they might also find something very significant to discuss. The point is simply that the matrix provides an order to the discussion so that opportunities to introduce key topics can be raised.

Although it is clear that Beauchamp and Childress introduced their four principles purely as a heuristic device for helping nonspecialists think and discuss ethical issues in a somewhat less haphazard fashion than they otherwise might have, the four principles have acquired a theory-like status of their own. As a result, philosophers and other scholars of bioethics now discuss and debate “principlism” as if this rubric were itself intended to be a comprehensive ethical theory. There is thus a risk that any procedural, discourse, or matrix-style approach to practical ethics will be derailed into a theoretical discussion. In this connection it is important that both Beauchamp and Childress, on the one hand, and the developers of the ethical matrix, on the other, have understood these rubrics to be somewhat flexible and have recognized that a rubric developed for one set of ethical questions (or one group of ethical discussants) might not be particularly useful or appropriate for another. For example, a discussion of genetic engineering applied to plants might well include “plant genomes” as a potentially affected type of entity, though it is less clear that plant genomes should be included in a discussion of alternatives for farm finance. Such flexibility is a strength of procedural or discourse approaches, but it does not lend itself to detailed theorization.

The Uniqueness of Agricultural Ethics

The last half century has witnessed the emergence of bioethics, environmental ethics, and business ethics as subfields in practical philosophy. Agricultural ethics has emerged more recently, along with numerous other contenders including research ethics, journalistic ethics, computer

ethics, and climate ethics. There is an obvious sense in which each of these fields reflects a vague demarcation of a certain subject matter. But it is also obvious that each of these fields can be defined more and less broadly. Van Rensselaer Potter (1911–2001) coined the term “bioethics” in 1970 with a stated intention that it include environmental as well as biomedical themes (Potter 1971). Within little more than a decade, common practice limited the term to biomedical issues, and very few people interested in the ethical dimensions of environmental topics were calling themselves bioethicists. In his 1995 book *The Spirit of the Soil*, Paul Thompson characterized agricultural ethics as a subfield of environmental ethics, though he also argued that agricultural questions were being neglected by the community of environmental philosophers (Thompson 1995). Many scholars working in agricultural or food ethics today would not associate their activity with the subfield of environmental philosophy.

One reason for claiming that an emergent domain of practical ethics is unique or special is that the questions it asks are new or have little precedent in the 3000-year history of philosophical ethics. For example, Holmes Rolston argued that environmental ethics was unique because it raised questions about the moral standing or status of nonhuman and even nonliving entities such as wilderness, endangered species, or ecosystems (Rolston 1975). No one has yet argued that agricultural ethics is novel or unique in this specific sense. On the one hand, some of the key questions in agricultural ethics, such as the sustainability of a production system, do have precedents even in the ancient world. On the other hand, even this age-old question is unlikely to be considered by specialists in many fields of practical ethics – including environmental ethics. In short, although there do not appear to be philosophical reasons for regarding agricultural ethics as a unique type of inquiry, the current disciplinary practice within philosophy and the various areas of practical ethics ensures that important questions relating to agriculture will *not* receive scholarly attention in the absence of agricultural ethics being defined and recognized as a distinct subfield.

The discussion of Singer and O’Neill given above shows that it is possible to see agriculture as a particular area in which classical approaches to philosophical ethics (such as consequentialism or deontology) are applied. However, some topics in agricultural ethics challenge the applied model. Since the earliest years of the twentieth century, philosophers working in ethics have recognized that intuitions – deeply held and seemingly involuntary reactions that people have toward specific cases – may conflict deeply with what a given ethical theory might say about proper action in a particular case. One area where intuitions have been discussed in agricultural ethics concerns the use of genetic engineering to address problems in animal welfare by making deep changes in the organisms that provide animal products such as meat, milk, and eggs. From the 1980s, Bernard Rollin has written a series of articles arguing that while a sound ethic for animal use requires respect for an animals’ *telos* – the genetically based drives that give rise to needs, interests, and typical behavior on a species by species basis – there would be nothing wrong with using genetic engineering to change an animal’s *telos* (Rollin 1995, 1998). But numerous philosophers have noted that the idea of using genetic engineering to create hens or pigs more tolerant of the crowded conditions on industrial livestock farms strikes most people as profoundly wrong (Bovenkirk and coauthors 2002; Fiester 2008). Even those who end up supporting such technology agree that there is something troubling about it, but because such a change would improve both aggregate and individual welfare, neither consequentialist nor deontological theory has an easy time explaining the source of this intuition.

There continue to be heated debates about the prevalence, meaning, and significance of intuitions among general ethicists, and the response to such intuitions often leads authors in agricultural ethics to evoke concepts from virtue theory – the third major tradition in ethical theory. Here, the claim is that actions such as genetic engineering to change animals (or even to improve crops) are morally suspect not so much because they harm or disrespect a moral subject, but because

the profit motive or disregard for common decency shows that the agent in question (the genetic engineer) has a defect of moral character. The ethical problem is not occasioned by an outcome (consequentialism) or by the violation of a right (deontology) but by some flaw in the motivations, habits, temperament, or mentality of the agent (Sandler 2005). Thus, here again a problem in agricultural ethics can be seen to be resolved by appealing to some more general theory – again an *application* of ethical theory. It is thus likely that many scholars working in agricultural ethics will continue to see their work as a form of applied ethical theory.

It is also possible to find discussions of agricultural topics distributed throughout the history of philosophy. Thus, someone knowledgeable about English land tenure disputes will see echoes of them in John Locke's development of the social contract, and scholars of John Stuart Mill will discover that he wrote a number of significant essays on the English Corn Laws, governing agricultural trade. Treatises on agriculture were written by Virgil and Xenophon, and Hegel's lectures on the philosophy of history begin with extended (if also somewhat imaginary) discussions of food production in Africa, Asia, and the Peloponnesian Peninsula. More recently, Michel Foucault weaves a discussion of Hesiod's discussion of agriculture into his analysis of Aristotle's formulation of "the will to know." As such, there is a wealth of material in the history of philosophy that might be included under the heading of agricultural ethics. To date, relatively few practitioners of contemporary agricultural ethics have seen fit to draw upon these historical precedents.

Summary

The definition or characterization of agricultural ethics is itself a metaphilosophical problem: One's answer to it will depend on what one takes ethics and/or philosophy to be. Discussion and debate among people holding different views or perspectives on the nature of ethics rapidly *becomes* a philosophical debate unto itself. This essay has

attempted to sketch some of the most prominent threads that might characterize such a debate. Certainly some philosophers writing on agricultural topics take themselves to be applying well-recognized approaches in ethical theory. However, it is noteworthy that many of the most frequent contributors of scholarly work in agricultural ethics seem to work from a more pragmatic or procedural orientation to their field. In either case, direct engagement with the metaphilosophical questions that arise in attempting to define or theoretically circumscribe the field of agricultural ethics are quite rare. This is in distinct contrast to environmental philosophy, where many have noted that the field does not seem able to move beyond highly theoretical debates about the nature of intrinsic vs. instrumental valuation in order to take up the ethical dimension of substantive environmental issues.

In conclusion, the field of agricultural ethics is perhaps best defined ostensively, that is, by indicating the work of its practitioners. In that, we return to the observation with which this essay began. It is the entire *Encyclopedia of Food and Agricultural Ethics* that best delimits and indicates the scope and nature of the field. Observing and analyzing the diverse activities of practitioners will yield the most perceptive and accurate account of what agricultural ethics is.

Introduction

Humans live in constant interaction with nature. That is part and parcel of being a biological creature on this planet. On one hand, humans exploit the available resources to survive, and at the same time, humans are deeply dependent on the continued capacity of nature to sustain their lives and the lives of their children and future generations. But something has changed over the past 50 years: Never before in human history have so many animal and plant species been made extinct so fast – and 10–30% of mammal, bird, and amphibian species are currently threatened with extinction; freshwater ecosystems are particularly at risk. Never before has humankind been so destructive and exploitative in relation to ecosystems and vital resources as now. Just as an example, in the last decades of the twentieth century, about 20% of the world's coral reefs and 35% of the mangrove areas were lost (Millennium Ecosystem Assessment 2005).

In the following, the development of agricultural science will be sketched out and the role of ethics in agricultural science will be discussed. Then different views of nature that have shaped agriculture and the role of science in agriculture will be discussed by analyzing some of the

presumptions behind the concept of ecosystem services and the way animals are viewed. Finally, the concepts of animal welfare and sustainability will be explored to show how they make vivid the connection between agricultural science and ethics.

The Development of Agricultural Science

Although the first traces of agricultural research can be traced back to the thirteenth and fourteenth century, organized agricultural sciences first emerged in the mid-1800s, primarily with increased mechanization and organization of agricultural production and the possibilities to make agriculture “rational” and the use of different technological inventions to increase productivity in agriculture and food production. In the late eighteenth century, chemical compositions of soil and systematic measures of the growth conditions of different crops started the chemical intervention in farming and hence the development of agronomy. The introduction of chemical and genetic control increased in the late 1800s and early 1900s. The development of scientific approaches to agricultural development can be seen as a contrast to the previous centuries’ practical development of farming, where knowledge and skills were passed on between generations on local context-specific levels. However, more systematic collection of information from farmers and dissemination of “best practice” in agricultural schools or published texts, e.g., initiated by progressive landowners, were also increasingly practiced from the seventeenth to the eighteenth century and improved production and knowledge in relation to agricultural challenges (Jones and Garforth 1997).

A boom in the development of agricultural production happened in the northwestern world in the post-Second World War era, where mechanization of agriculture increased dramatically and the Western European agenda was to ensure food security for the population, as increased welfare was seen as one way to avoid wars and conflicts in the future. In this phase, agricultural research stations and institutions grew and were viewed as

necessary instruments to an increased production through a “rational growth agenda.” In the following decades, subsidized farming in parts of Europe and North America became increasingly specialized and industrialized and continued to increase in productivity, while at the same time international trade grew larger. In other parts of the world, e.g., India and Mexico, so-called green revolutions of agriculture involving hybrid seeds, mineral fertilizer, and pesticide use introduced mainly at the larger farms resulted in major increases in agricultural productivity and at the same time had severe long-term impacts on soil degradation and environment (Cullather 2010). In the past decades, agricultural and food systems have been influenced by an enormous growth of transnational food corporations, liberalization of international food trade and foreign direct investments, and increased globalization of the diet (Hawkes et al. 2009). The food and agricultural industry has supported research which influences this development (Lesser et al. 2007), both through establishing own research units and funding to universities and other research institutions through various channels. Out of this, at least two major trends in agricultural research have developed:

1. Research which is more or less guided and controlled by large private companies like Monsanto (Robin 2010) that seeks to develop products such as agrochemicals and patented seeds to agricultural and food systems which meet the demand for huge amounts of cheap food products
2. Research which focuses on critical issues in relation to the industrialized agriculture and food systems and have the potential to inspire changes of farming practices toward a more environmentally and socially responsible agricultural sector

The latter includes: Research in climate change, biodiversity, social aspects of farming, and governance of food chains that have led to a value-based critique of, e.g., growing reliance on experts and increased vulnerability of farmers, science-techno-based farming, intellectual

property rights, and labor conditions (Beus and Dunlap 2010; Thompson and Stout 1991).

The Role of Ethics in Agricultural Science

The understanding of agricultural science developed above makes it obvious that there is a strong link between agricultural science and ethics, since the goals of agriculture and the choice of strategies on how to obtain them are not themselves only scientific questions but also questions that require answers based on value. These are questions as what kind of foods to produce (animal products or vegetarian), which methods to use (organic, conventional, extensive, intensive, biodynamic), what consequences of human action to accept (landscape, animal welfare, wildlife, environment), and what conditions to provide for farmers, farmworkers, and all others working on the land and in the food-producing sector (health, social status, rights). These questions can only be answered through ethical considerations and reflections and not through natural sciences. The ethical discussions include a discussion of who can legitimately answer these questions. Or, in other words, who should govern the land? Is it a political task, should it be through participation from civil society actors, or should it be left to the market and thus be decided through the often silent negotiation between producers and customers? In the latter scenario, there is a risk that decisions are shaped in the space between a commercialized market and individual consumers left to fight for their values with their wallets. This is not unproblematic as the outcome of this negotiation is also of obvious interest for those who are not part of it and have no voice: the poor, future generations, animals, plants, and ecosystems.

Such questions reach into the area of political and societal structures and are thus often not seen as part of agricultural sciences, despite the fact that the structure and governance of agriculture itself strongly influence the way in which we ask scientific questions and vice versa. This is not surprising, since the perceptions and goals of scientists are just as full of value assumptions as the goals of politicians. Objectivity in science does

not cover the goals of science but only the methodologies, where, e.g., data can be described in terms of repeatability and reliability, but the choice of how and which data to collect, focus on, and analyze is still a choice of each researcher or research team and should be communicated as such. Further along these tracks lie the questions of how risks are understood and communicated and how the interpretation of scientific uncertainty influences the way that scientific results are presented (Webster 2003).

Describing the relationship between agricultural science and ethics entails recognizing the ways in which values penetrate agricultural sciences and determine goals and methodologies. The classic notion of an objective science that develops technologies, which the civil society then choose from, is replaced with an understanding where science is seen as embedded within the social framework through which complicated interactions shape the more-than-human life-world. Thus, from a moral and social point of view, agricultural scientists have an obligation to be transparent about the assumptions underlying their work as their results and advice are expressions not only of knowledge but also of values.

Agricultural science can enhance understanding of important aspects of the soil and ecosystems on which humans are dependent for food and – to a growing extent – energy. Agricultural sciences participate in collecting, systematizing, and transforming practical knowledge and skills of farmers and agricultural professionals into more time- and/or cost-efficient practices and technologies and in inventing new technologies and machines which can increase efficiency in different ways (Tilman et al. 2002). As long as this is not connected to funds for inventing tools or patents that only benefit few, distort power relationships, etc., and it is clear and transparent; then it is quite simply a generally accepted feature of scientific approaches.

It becomes problematic, however, when there is a move from *methodological reductionism* and into *ontological reductionism*. Methodological reduction is a necessary prerequisite of science, by which certain aspects of the phenomena being examined are excluded/deliberately ignored to

achieve objectivity or at least intersubjectivity in a group or community of science. Ontological reductionism occurs when the results from a specific scientific inquiry are viewed as the only valid knowledge about a given phenomenon, no matter the context. The context in a complex world (e.g., a farm) can be very different – and hence influence and interact in different ways – from the quite controlled environment in which the phenomenon was studied. In such a case, the world itself is reduced, and every part is seen as a simple sum of smaller parts, which can be studied independent of their context (Fang 2011). This could, for example, be a study of how certain plants grow and thrive being provided with different levels of a certain type of nutrient under controlled conditions in a laboratory. The results of these studies are valid under similar conditions, but plants of the same species and variety may turn out completely different in relation to the same type of nutrient under different on-farm conditions, where they are not only influenced by these studied nutrients but also by, e.g., temperature, seasons, other trees, plants, and management practices which were not present in the laboratory.

The same move can be seen within agricultural science when the basic ethical relationship between humans and nature is denied on the basis of the results of an agricultural science that from the outset looks away from this relationship to enable a scientific inquiry. How agricultural science is done both from a teleological and methodological perspective is thus very dependent upon the view of nature presupposed in the scientific work.

Views of Nature

Humans have lived with, in, and from nature for thousands of years and increasingly transformed what formerly was “living on the mercy of nature” into “taking control and shaping agricultural systems.” This has happened in different ways: In some cases, it has been based on a rather interaction-based view and practical approach, such as shaping systems which build on or mimic the mechanisms of natural ecosystems,

e.g., permaculture and certain agroforestry systems. In other cases, it has been based on a more control-based view, where humans aim at getting the full control over land, plants, animals, and agriculture and use the resources around them. These different approaches are built on different views and values related to “what nature is” and how the relationship between humans and nature should be seen.

A dichotomy between “nature” and “culture” is often taken for granted. However, “nature” and “culture” are mixed into new forms as new hybrids are produced in agriculture and agricultural sciences. For example, in the meeting between the farming landscape and nature, “nature” is guided and restricted by agricultural activities. Yet the existence of a “nature” which can be distinguished from “culture” is often emphasized.

Within environmental philosophy, a distinction between views that are mainly anthropocentric, pathocentric, biocentric, and ecocentric has been developed – the latter also sometimes religiously inspired from especially animistic traditions (Abram 1996; Griffiths 2006). Each viewpoint describes the kind of entities that are seen as members of the ethical community (Krebs 1999). These basic views influence the ways farmed landscapes and animals are perceived and shape the understanding of which responsibilities humans have and how to interact with nature. “Nature” is a complex concept with many layers of meaning. Some of the qualities linked to nature are, for example, described as (a) wilderness, e.g., the quality of natural processes not disturbed by human interference including pollution; (b) continuity, e.g., that a habitat is allowed to exist over long time; (c) authenticity, meaning that “nature” is not constructed or planned; and (d) originality, understood as nature with native species and habitats (Tybirk et al. 2004). Different basic views on nature can be described, for example, a “naturalist view” (where all four described dimensions are present and humans should protect natural areas and manage seminatural areas very carefully); an “ecologist view” in which humankind can interact, structure, and “enhance” natural processes also in relation to agricultural activities; and a

“cultivist view,” where nature is only found outside farmed land areas.

The concept of ecosystem services vividly illustrates how farmed and nonfarmed land is viewed within an anthropocentric framework. If humans do not interact with or “use the services” of nature, then it is basically without interest, as it is of no “service.” The microbiological life in the soil can be viewed as such an ecosystem service: Without this life – which consists of “natural microorganisms” – cultivated plants cannot grow well. The goal from an anthropocentric point of view therefore becomes to control and preferably improve the microbiological life in the soil to enhance the ecosystem services that it provides. This can be seen as a contrast to the deep ecology philosophy, which insists on the inherent value and worth of every living organism in their own right.

Pollination is another example of an ecosystem service, on which agriculture is deeply dependent – about 70% of the global plant production relies on pollination, so if the bees die, food production will be gravely challenged. Scarily enough this has been the case since the beginning of this century. The phenomena – labeled as colony collapse disorder (CCD) – were first reported in the USA and then spread to Europe. The reasons behind the vanishing of bees are still not entirely understood, but human actions, especially the use of pesticides and herbicides, are suspected as major factors (Suryanarayanan and Kleinman 2013). One response to the increasing threat to bees has been a suggestion to invent “robot bees” (Anonymous 2012; Steadman 2012). Such an attempt to “repair” a problem that is most likely created by human action clearly comes from the anthropocentric and cultivist side of the value landscape. The role of science (agricultural, biological, and engineer sciences) is seen as inventing such robot bees, and the role of the industry is to market something which before was an “ecosystem service.” From a more ecocentric view on agricultural sciences, solutions would aim at creating agricultural systems which respect animals and the living communities that they are embedded in and help create conditions, allowing and supporting the pollinators to work and live as part of an organically sustainable system.

Views of Animals

Through domestication and breeding, humans have for thousands of years increasingly shaped animals to more efficiently produce meat and other animal products. This development has escalated since the intensification of animal production in the 1950s and raises a range of ethical issues. In intensive animal production systems, animals have been bred to grow faster and produce more, leading to a range of production-based welfare problems (Gamborg and Sandøe 2005). Discussions of sustainability within animal breeding clearly show that the narrow focus of production efficiency has been a mistake – although the long-term goal of breeding is still to ensure the economic sustainability of the production. Thus, economic concerns and not environmental or welfare concerns rule the day. Only to the extent that environmental considerations or animal welfare concerns are compatible with this overall goal, a growing interest in the environment or welfare of the animals can be expected.

Besides breeding the animals to fit the production facilities better, the animals are also “shaped” by more direct methods: They are cut and shaped so as to allow farmers to keep them under very restrictive conditions – cows are dehorned; pigs have their teeth, tail, and testicles cut; and poultry have their beaks trimmed. All this is done to ameliorate the physical damage which they can make on themselves and each other – often as a result of the stress caused by the inability to perform their species-specific behavior: The animals still have basic needs such as need for a certain space around them, for territories, for foraging, for a hierarchy, and for sexuality, just to mention some. Agricultural animal research has to a large degree been directed toward developing animals that fit into predefined production systems and at the same time yield and grow at a maximum rate. “Farms” have turned into production facilities and the understanding of the animals changed so that they are seen as production units and described in terms of kilograms rather than living individuals (Anneberg 2013). This process has been most visible within the poultry, egg, and swine industry,

but the production of milk and beef is following the same tracks.

Farm animals, even though they have been selected and bred during many generations to fit as smoothly into the production systems as possible, still have species-specific behaviors that are not possible to perform in the intensive production systems. They compensate by showing stereotypical behavior. An example is a sow’s needs to build a nest before farrowing: She shows this behavior even when completely restricted between iron bars on concrete floor, where she does not have the physical material to build this nest. The compromises between the needs of the animals and the degree to which these are met in production systems are thus partly guided and informed scientifically through a wealth of studies on animal diseases, production, behavior, and other things. Agricultural sciences have participated in the development of the concept of animal welfare and have developed a number of different schools and definitions of animal welfare (Haynes 2008). This science can be characterized as a mandated science, meaning science with the purpose of informing political debates and decision-making (Fraser 2008). Scientific studies have also participated in the development of so-called animal welfare assessments, which is part of the development of the current animal production systems. The concept of animal welfare is thus used and shaped by a huge number of different stakeholders as a marketing tool, to formulate regulation and to influence the public debate.

Animal Welfare as an Example of an Agricultural Scientific Field

The concept “animal welfare” can be viewed as an example of a scientific approach to handle the increased industrialization of animal production and the increased concerns about this production and the well-being of the animals. “Justice” to animals was discussed already back in the ancient Greece, and animals have been “subjects for protection” in legislation for a couple of centuries, mostly in terms of “unnecessary cruelty to

animals,” e.g., beating horses. However, the type of suffering linked to restrictions in not meeting the animals’ natural needs and allowing them natural behavior, access to space, and systematic mutilations such as beak trimming, tail docking, and dehorning has become an issue both in the public debate and in science from the 1950s and onward. One of the first books on the effects on animals of intensive farming that lit the spark to the debate was *Animal Machines: The New Factory Farming Industry* by Ruth Harrison in 1964 (Harrison 1964), which among other things led to the so-called Brambell Report, on which some of the animal welfare principles were built.

The concept of “animal welfare” is an interesting example of a mandated science, where scientific factorial knowledge, e.g., about animal behavior or the presence of disease, is constantly intertwined with ethical considerations and understandings of “what is good or bad for the animals.” This is obviously perceived differently in different historic and cultural contexts.

Within the “animal welfare science,” different animal welfare assessment systems are developed. The choice of focus and detailed parameters in such assessment systems are made with scientific studies as background. This scientific knowledge can be “delivered” to inform and give arguments for ethical considerations and decisions of what is acceptable for animal farming and to create certain norms within the context in which the systems are being used. However, this does not remove the choices of the scientists: These choices are inevitably taken partly on background of their perceptions of what animal welfare is. Studies have been made to develop “animal welfare assessment” in caged hens systems focusing on advantages and disadvantages of different cage systems, where some researchers will study feather coats and egg production and relate “animal welfare” to such parameters, and other actors will claim that it is not possible to talk about “animal welfare” in a system which restricts natural behavior and ask whether it would not make more sense from an animal welfare point of view to question whether caged systems are “fair” to living animals at all. Here the question also becomes what the relationship is between the

fields of “animal welfare” and “animal ethics” (Yeates et al. 2011).

The welfare of farm animals must be understood as both a normative ethical concept and a scientific field of inquiry. It is a clear example of a field where the methodological choices made before the research can be done are strongly dependent on the ethical values of the researcher (Fraser 2008). Some have claimed that “animal welfare” can be seen as a social technology, which participates in a basic “scientific legitimization” of industrialized farming systems and that a focus on “animal welfare” among the involved professionals can help create trust among nonprofessionals (consumers/citizens) that “animal welfare is taken care of” (Anneberg 2013).

Sustainability

The concept of “sustainability” has been more or less intuitively understood and practiced during centuries by people who were living closely in and dependent from the surrounding nature, as “the responsibility to act so that the seventh generation from now could still sustain itself.” The concept of “sustainability” as used today arose in the forestry industry more than 200 years ago and has since grown almost organically into a multifaceted and complex concept (Wiersum 1995). In 1987 the United Nations placed the concept in the middle of discussions on environmental management through the Brundtland Report. Here sustainability is understood as “... a development that meets the needs of the present without compromising the ability of future generations to meet their own needs” (United Nations 1987).

Since then the concept of sustainability has been developed and discussed scientifically and in societal debates as a response to the challenge of feeding an increasing population of humans in an ecologically responsible and just way at the same time significantly reducing our short- and long-term environmental impact. Clearly, this debate is closely interlinked with how food is produced and distributed. To an increasing degree, this happens in the light of the changing climate that is both a threat to current production

and to a large extent a result of it (Steinfeld et al. 2006).

In most currently used definitions of sustainability, at least three pillars are acknowledged as constituting the concept of sustainability: an economical aspect, an ecological (environmental) aspect, and a social aspect. Recently, a fourth distinct pillar has been included by some authors, namely, the institutional aspect. The understanding of the concept – including the pillars and their interconnectedness – is nevertheless hugely disputed because different actors and organizations can define, understand, and use it in different ways and place weight on the pillars differently and in accordance with specific interests (Valentin and Spangenberg 2000).

The whole issue of designing agricultural and food systems to be sustainable is extremely complex and involves many players – in the end everybody, because everyone eats food, and all humans can be considered citizens. Agricultural sciences typically focus on the production aspects, based on the argument that there is a need to feed nine billion people in a few decades. This has, however, been criticized as too narrow a view of the issue as it seemingly ignores that food production per capita has never been higher and issues of distribution, the complex picture of food trade systems, food waste, ethical considerations related to industrialized agriculture, land rights, and a steadily increasing consumption of animal products are not seen as part of the context of the problem (Mephram 1996). What sustainability is and how to balance the emphasis on the four pillars in a given context thus need to be decided on an ethical and political basis, before agricultural science can begin to provide answers. Science is a tool, but before using it, it needs to be decided what it is to be used for.

Summary

Discussing sustainability and animal welfare within the context of agricultural science entails a lot of ethical reflection as many of the assumptions about what the concepts cover, how they should be scientifically examined, and what

goals they should be directed against are based on values. Agricultural science is, as any other science, performed in a social and cultural context and therefore embedded in values. Agricultural science is a very important factor in the current situation where a growing population, increased pressure on resources, climate change, genetically modified plants for human consumption, production of plant-based biofuels, and further intensification of animal production with growing welfare problems as a likely result challenge societies. But it is important to realize that the way these issues are approached and the solutions that are suggested by scientists are part not only of a scientific inquiry but also a societal and ethical discussion on how human beings should relate to animals and the rest of nature.

Introduction

Agricultural science can be broadly understood as the application of scientific methods and methodologies to improve agricultural practices, including the harvesting, processing, and distribution of food, fiber, and pharmaceutical products (Noll 2015; Olmstead and Rhode 2008). This field historically focused on a wide array of research topics, such as improving production techniques, controlling pests, minimizing the effects of drought, the selective breeding of plants and animals, and research on various socioeconomic topics. It is a multidisciplinary area of research that includes work in both the natural and social sciences and integrates methods originally developed in distinct fields. Indeed, the process of improving agricultural practice often involves the combined efforts of researchers working out of diverse disciplines, such as agronomy, chemistry, ecology, soil science, and the social sciences (Jacobs and Frickel 2009). For this reason, “agricultural science” should be understood as an

umbrella term that includes work coming out of various scientific disciplines, albeit with the singular aim of improving agriculture.

This entry discusses the connections between values and agricultural science largely in the context of the United States. The first section provides a brief overview of the historical development of agricultural science, as this background is imperative for understanding how values influence the agricultural sciences. The next section outlines a definition of “values,” before moving on to discuss how shifting societal priorities and concerns influence the scope of research questions and agendas in agricultural science. The final section discusses how expanding and shifting value claims have impacted current research agendas. Today, agricultural scientists are conducting cutting-edge research guided by goals well beyond increasing production. As this entry discusses, the current needs of the larger community of farmers, citizens, and consumers are often reflected in this work.

Historical Roots of Agricultural Science

The practice of applying empirical methods to improve agriculture has a long history well beyond the context of the United States. For example, Xenophon (444–375 B.C.) and Aristotle (384–322 B.C.) both wrote extensively on agriculture and the Romans developed sophisticated agricultural methods, specialized animal breeds and crops, and conducted experiments aimed at improving farming methods (Kingsbury 2009). However, it was not until the Enlightenment that modern scientific methods and methodologies were applied to agriculture in earnest, with the express purpose of improving crop yields, increasing mechanization, and generally improving agricultural systems, as a whole (Brantz 2011). The Scientific and Industrial Revolutions of the eighteenth century then combined to further this research, with Europe reaping the tangible benefits of a significant increase in the availability of food and the reduction of the numbers of workers needed to work the land (Kingsbury 2009).

In the United States, governmental support kick started agricultural research during the latter

half of the nineteenth century (Rosenberg 1997). Agricultural science became institutionalized during this time period with the establishment of land grant universities and federally funded experiment stations (Hillison 1996). Specifically, the Morrill Act of 1862 provided the funds to endow land grant institutions. Unlike many higher learning institutions of the time, these universities shared the mission of training students in practical pursuits, such as agriculture, science, and engineering. Later the Hatch Act of 1887 and the Smith-Lever Act of 1914 expanded this effort by providing states with federal funds to establish experiment stations and extension services, with the express purpose of training farmers in new agriculture methods and best practices.

Indeed, land grant institutions and experiment stations form part of what David MacKenzie (1991) calls the Triangular Partnership (or Three-Way Partnership) that has historically supported cutting-edge agricultural research in the United States. Very roughly, this partnership consists of government agencies that fund research projects in agriculture, universities that conduct research aimed at improving agricultural practices, and extension services that pass these innovations on to farmers. Indeed, Rosenberg (1997) argues that the role of experiment stations was apparent since their inception: “It was to perform the experiments which the individual farmer, lacking time and opportunity, could not” (p. 154). In conjunction, the role of extension services is to disseminate the results of these experiments and various other advances that could improve farming practices in regional contexts (Thompson and Noll 2015). It is important to note here that this partnership is not one directional, as farmers can comment on which projects should be funded and often recommend potential research projects to extension officers and researchers in the field. This is a significant point, as agricultural research, especially in the United States, is meant to benefit farmers and society (Rosenberg 1997). The next section of this entry will discuss the connection between agricultural sciences and values. However, it is important to first define what is meant by the term “values.”

Agricultural Science and Values

For the purposes of this entry, “values” should be understood very generally as (1) rules that guide human action and (2) commitments concerning the worth or importance of something (Anderson 1993; Zimmerman 2015). While the first definition plays an important role in moral theory, the second definition encompasses how commitments guide action and decision-making in various contexts including the choice of research agendas (Douglas 2009; Kourany 2010). These commitments predominantly take the following two forms: (1) something is intrinsically valuable or valuable for its own sake and (2) something is extrinsically valuable or valuable because it is a means to a desirable end. For example, one could argue that a domesticated animal, such as cow or a pig, is valuable for its own sake because it is a “subject of a life” or is sentient (Regan 2004). In contrast, one could argue that this same animal is valuable because it provides milk, meat, or another product that we find useful. In the first argument, the person is making an intrinsic value claim, while in the second argument, she is making an extrinsic value claim. Historically, intrinsic value was thought to form the foundation of ethical claims, as individuals with intrinsic value were thought to have ethical standing, while individuals without intrinsic value were thought to lie outside the ethical sphere (Zimmerman 2015). In fact, Plato [428–347 B.C.E.] wrote extensively on this topic, as did Aristotle, G. E. Moore [1873–1958], Kant [1724–1804], and more recently Roderick Chisholm [1916–1999] and many others.

As the above outline of the history of agricultural science in the United States intimates, extrinsic values play an important role in guiding agricultural sciences. For example, since the Enlightenment, scientific methods were applied in earnest to agriculture with the express purpose of bringing about some improvement or “good,” such as the improvement of soil fertility, effective use of cover crops, or the development of a four-course rotation system, for example (Brantz 2011). In turn, these research goals ultimately contributed to the achievement of larger societal

goals, such as making food more readily available to citizens, increasing available capital in rural areas, or freeing up labor from the land, so that workers can pursue other pursuits. In fact, the development of the Triangular Partnership in the United States was guided by the expressed view that social resources should be used to support various social goods (Rosenberg 1997).

As argued by Paul Thompson and Samantha Noll (2015), in this context, “*the influence of publicly organized research conducted at experiment stations... provide the basis for viewing agricultural science... as an applied science with explicit value commitments*” (p. 1022). One of the basic commitments of early agricultural scientists is the view that we should increase agricultural production (Rosenberg 1997), as food, fiber, and pharmaceutical products are of paramount importance when meeting basic human needs and thus have extrinsic value. This commitment to increase agricultural production also illustrates how intrinsic values play an important role in guiding agricultural research, as food and fiber products have extrinsic value because they play important roles in sustaining human life, which is often understood to have intrinsic value or value in itself. As food is imperative for human survival, it is important or is a “public good” to use science to increase food production.

Current Impacts of Values on Agricultural Sciences

Just as the agricultural sciences were historically guided by the goal of increasing production, society is increasingly accepting expanded intrinsic and extrinsic claims (such as that ecosystems and animals are worthy of consideration) and agricultural research goals are shifting to include a wide array of new research questions and goals. These influences predominantly stem from (1) social movements surrounding food that influence food policy and (2) social and ethical critiques of agricultural sciences (Noll 2015). For example, the local food movement, “locavore” trend, and similar social initiatives surrounding food systems have increased the economic

demand for “organic,” “sustainable,” and environmentally responsible agricultural products. These social movements are guided by various value commitments, such as a concern for the environment, animal welfare concerns, the desire to support local farmers, food access issues in urban areas, and health and food contamination concerns (Feenstra 2002; Lyson 2004). Changes like these in social contexts often impact current agricultural science at land grant institutions, as the explicit goals of these institutions include performing research useful for local farmers (who are impacted by consumer choice) and supporting rural economies (Rosenberg 1997; Noll 2015). For these reasons, an increased demand for such research, when voiced by farmers and consumers, can justify new research on alternative methods of production, such as organic and small-scale production, and agricultural systems that cursorily meet current consumer standards and values. When translated into research agendas, such work can be understood to be impacted by the social and economic forces that brought it about.

Additionally, this research trend can also be seen as at least partially the result of growing critiques of the agricultural sciences. Indeed, entire fields of research developed in response to growing criticisms of the research priorities and impacts of agricultural science (Thompson et al. 1991; Johnson 1984; Dahlberg 1988). Especially prominent debates include those on the potential impacts of genetically modified crops (Doyle 1985), various environmental impacts (Jackson and Jackson 2002; Shiva 1992) of industrial farming systems, animal welfare concerns (Regan 2004; Rollin 2003), the plight of local farmers (MacKenzie 1991; Hightower 1975), and a plethora of other social concerns (Hightower 1975; Jackson 1980). In each of these examples, the previously unproblematic goal of increasing production was challenged, as this mandate came into conflict with other values, goals, or potentially caused problematic consequences. While one of the dominant themes guiding agricultural science is still improving the availability of food and fiber products and lowering the costs of these staples (Thompson et al. 1991), researchers have become increasingly

interested in determining whether or not the above critiques are accurate and, if so, the extent of the various impacts.

This shift in agricultural science, from focusing on increasing production to doing research on social and ethical impacts, began in earnest around the 1970s, with scholars such as Glenn L. Johnson (1918–2003), Wendell Berry (1977–), and Rachel Carson (1907–1964) publishing articles calling for greater attention to normative and environmental issues surrounding agricultural sciences. More recently, research on wildlife conservation on farmland, biodiversity management, and mitigating human-animal tensions is on the rise, with the Rodale Institute and the Oxford University Wildlife Conservation Research Unit (Macdonald et al. 2015) running long-term experiments in these areas. There is also a plethora of work examining normative concerns, such as that which focuses on local food initiatives (Delind 2011; Shicca 2012), selective breeding and genetic modification (Boyd 2001; Greger 2011), and the impacts of policy changes on farming practices (Fairlie 2010). This trend in agricultural research illustrates how many research administrators and scientists have accepted the call for agriculture research to address a larger spectrum of social goals beyond the increase of production.

Conclusion

As discussed in this entry, agricultural science is an applied science guided by implicit and explicit value commitments. Historically, this translated into research on increasing agricultural production and reducing the numbers of people needed to work the land (Rosenberg 1997). In contrast, today agricultural scientists are conducting cutting-edge research guided by social goals well beyond crop yields, such as improving the sustainability of farming practices, fighting desertification, mitigating climate change, and conserving biodiversity. As the history of agriculture science illustrates, this field is unique as it often applies modern scientific methods to help meet the needs and goals of the larger community of farmers, citizens, and consumers.

Summary

This entry provided a detailed overview of how values inform agricultural science. As discussed, “agricultural science” can be broadly understood as the application of scientific methods and methodologies to improve agricultural practices, including but not limited to food production, processing, and distribution. It is a multidisciplinary area of research that involves the combined efforts of researchers working out of diverse disciplines. This entry was broken down into succinct sections, each outlining an important aspect of agricultural science and values. In particular, section one provided a brief overview of the historical development of agricultural science. Section two includes a definition of “values,” before providing a description of how shifting societal priorities and concerns influence the scope of research questions in agricultural science. The final section discussed how expanding value claims impacts current research agendas. Today, agricultural scientists are conducting cutting-edge research guided by values and goals well beyond production concerns, such as the current needs of farming communities, citizens, and consumers.

Bioenergy; Biomass; Energy crops; Food versus fuel; Land use change

Introduction

The non-food sector has always been an important part of agriculture providing fuel, fiber, building materials, and medicine among other resources.

Agricultural sciences have focused on the non-food sector in recent years as a means for societies to replace fossil fuels with more sustainable alternatives. This entry will give a brief history of agricultural sciences and non-food production, highlighting the recent increased production of biofuels and the “bio-based economy.” It will focus on the use of agricultural biomass (any organic matter that is living or was once living) as a transport fuel, what is commonly referred to as biofuels. These will be considered under the headings of energy crops and crop residues. The term “agricultural sciences” is used to refer to the application of natural, social, and economic sciences to the further development and understanding of agriculture. Thus, natural, social, and economic sciences have been involved in attempts to develop non-food agricultural products to address societal needs and in highlighting and analyzing controversies, developments, and trends within this sector.

Biofuels have been a particularly controversial area from the mid-2000 that has focused attention on the ethical aspects of non-food production. They incurred significant environmental impacts and were seen to compete with food production. Agricultural research on “first-generation” food-based biofuel was within what de Lattre-Gasquet et al. call the “productivist ethos” of increasing production and stabilizing prices (2010, p. 309). Science then also played a role in questioning the environmental and social credentials of biofuels. These biofuels not only faced issues of inequality and environmental destruction in line with other conventional, industrial-agricultural production of food but also undermined the productivist ethos of producing more food, by being seen to divert food from the food market to the fuel market (Thompson 2008a).

The increased demand for non-food agricultural products is seen by many as a challenge, given previous controversies around biofuels and ever increasing resource constraints. It is also seen as an opportunity for further development of agriculture, with a move away from using food crops towards non-food crops and residues and coproducts. Some view this opportunity as calling for agricultural scientific research within an industrial, intensive model that promotes efficiency.

Others see it as an opportunity to tackle environmental issues and inequality by moving agriculture towards an agroecological model.

History of Agricultural Sciences and Non-Food Crops and the Growth of the Bio-Based Economy

Humans have been dependent on agriculture to supply non-food products for millennia. In prehistoric times people used plants and animals for fiber; obtained fuel from wood, vegetable oils, and animal fats; and obtained medicine from a variety of plants (Fuller et al. 1996). Agricultural technology changed little between 1000 BC and 1500 AD, although certain non-food crops such as tobacco were introduced to the west (Fuller et al. 1996). The onset of the industrial revolution in the nineteenth century in the global north saw an expansion in scientific development within agriculture and the potential to produce far more non-food goods. This can be seen in the early twentieth century when Henry Ford produced his new V-8 car featuring plastic components and paint made from soybeans. Plant fuels could be used to power vehicles; the diesel engine unveiled by Rudolf Diesel in 1900 ran on peanut oil. The industrial revolution also meant the availability of cheap and abundant fossil fuels and agricultural products often found it difficult to compete. Fossil fuels became the dominant supplier of transport fuels.

The 1973/1974 oil crisis focused attention on fossil fuel dependence and created some renewed interest in biofuels. Brazil was one of the earliest countries to respond to this concern and establish a national biofuel policy producing bioethanol from sugarcane. During the first decade of the twenty-first century, many other countries, including the USA and EU countries, followed suit and developed biofuel targets. There was much initial optimism about biofuel's potential, with many seeing them as a way science and technology could be used to address the issues of climate change mitigation, energy security and independence, and rural development (Landeweerd et al. 2009). Biomass was initially seen as a carbon neutral alternative to fossil fuels because it stores

carbon as it grows, which is then released into the atmosphere when the biomass is burned; it can be grown in the country of use and also can provide an additional source of income for farmers. Government subsidies and incentives created a market for biofuels and production increased significantly during the 2000s. The USA and Brazil are currently the largest producers of bioethanol with the majority of biodiesel produced in the EU, Malaysia, and Indonesia. Biofuels from food crops currently make up a small proportion of transport fuels, for example, among the EU 27 2.5% of transport fuels are biofuels (Nuffield Council on Bioethics 2011).

The increased production of fuel from agricultural produce can be seen in the wider context of replacing fossil fuels with "greener" agricultural produce, what has been termed the "bio-based economy." Work is underway within the agricultural sciences to develop further agricultural applications in energy, chemicals, and advanced materials from food and non-food crops for industries such as construction and manufacturing (FAO 2012). These are promoted as having lower greenhouse gas emissions and higher energy efficiency than fossil fuels, as well as being biodegradable. The concept of the oil refinery is transferred to agriculture, with the "biorefinery" proposed as a way to extract every ounce of value from agricultural produce.

The above story is not equally true for all parts of the world, however, as many areas are still awaiting or in the midst of an industrial revolution. Ninety percent of the biomass for energy used globally consists of charcoal, dung, residues, and waste combustion in the global South in conditions of energy poverty (Schubert et al. 2008). Countries in the global South do play a role in the global non-food sector; however, they currently dominate the production of natural fibers from jute, sisal, and hemp (FAO 2012).

Energy Crops

Biofuels from Food Crops

This section will focus on energy crops used as biofuels in order to illustrate some of the ethical

issues raised by non-food crop production and the role of agricultural sciences. The agricultural science these crops are based on is not new; the technologies have long been in existence: starch from crops such as sugarcane, wheat, or corn is fermented into ethanol and used instead of petrol, or oil crops such as rapeseed oil, palm oil, and vegetable are used in diesel engines with only minor alterations. Research and development (R&D) into energy crops was undertaken within universities and private companies, incentivized by the need to meet government targets. Multinational agribusiness, biotechnology, car manufacturing, and dedicated biofuel companies have undertaken work on biofuels, as well as large oil companies such as Shell and BP.

Some contend that the ethos behind the agricultural science was also not new. De Lattre-Gasquet et al. (2010) state that in France the ethos was that of productivism based on the post-war time principles of increasing production, stabilizing prices, and ensuring supply. Thompson (2008b) also states that in the USA corn-based ethanol was developed within the industrial, productivist model of agriculture which emphasizes efficiency. This story is similar in other countries, with the majority of Brazilian sugarcane ethanol being produced within an industrial model of agriculture and government incentives in many African countries promoting large-scale production systems (Amigun et al. 2011).

The initial optimism over biofuels and the prospects of a win-win-win outcome gave way to controversy and criticism as it was claimed that biofuels competed with food production, were very environmentally damaging, and were produced in conditions of social inequality and injustice.

Ethical Issues: Food Versus Fuel

2007 and 2008 saw food riots in numerous countries because of a sudden increase in food prices. Many commentators blamed this price spike partly or wholly on the diversion of staple food crops such as corn and wheat from the food market to the biofuel market, what has been dubbed the “food versus fuel” controversy. In October 2007 Jean Ziegler the UN special rapporteur on the right to food stated, “It is a crime against

humanity to divert arable land to the production of crops which are then burned for fuel” (BBC 2007). Many NGOs made biofuel an important campaigning issue and linked up with food companies to press governments for the removal of biofuel targets. The issue became increasingly controversial with the right to food of the poorest contrasted with the desire of the rich to drive their cars and biofuels generally framed as an unethical, unacceptable technology (Nuffield Council on Bioethics 2011).

The role biofuels played in raising food prices has been disputed. There were many causes attributed to the price spike such as speculation on agricultural markets, poor harvests, low grain stocks, and rising fossil fuel prices, with different estimates of the exact responsibility of biofuels (FAO 2008). Some maintain that the food versus fuel controversy oversimplifies the debate, contending that the food crisis had been building for decades, with vulnerable countries becoming net food importers and the problem is not only one of supply and demand but also of a political-economic problem of access to food (Thompson 2008a).

Others have taken a different view of the issue and frame biofuels as a potential opportunity for agriculture, and even food production, in the global South (FAO 2008). They state that biofuels could prompt the research and investment needed to develop struggling agricultural markets. The global South could leapfrog the “dirty” fossil fuel-based technologies used in the global North and concentrate on bio-based alternatives. Ewing and Msangi (2009) state that there are numerous examples of small-scale bioenergy production in developing countries to benefit the poorest. They state, however, that barriers exist to their further development such as access to capital, technology, and secure land tenure. They also state that the benefits of large-scale developments can bypass the small-scale producers who make up the majority in these countries.

Environmental Controversies

While biofuels were initially promoted as a scientific solution to environmental issues, science also played a role in highlighting biofuel’s hidden

environmental impacts. Since current biofuels are made from food crops, they have followed the same industrial trajectory as other food crops produced in the global North (Thompson 2008b). Industrial production requires large amount of inputs in the form of fossil fuels, pesticides, herbicides, and fertilizer which result in local environmental impacts. The large embedded fossil fuel footprint has meant the resulting energy produced: the balance of energy input to energy output achieved can be minimal, depending on the crop in question (FAO 2008). Embedded carbon emissions and nitrogen oxide emissions from fertilizer use have also significantly reduced biofuel's greenhouse gas savings.

It has also been reported that some biofuel crops are grown on deforested land, such as palm oil production in Malaysia, resulting in more biodiversity loss and carbon emissions – a problem termed direct land use change (dLUC) (Nuffield Council on Bioethics 2011). A number of studies also emerged modeling the problem of what is called “indirect land use change” (iLUC). This is the phenomenon whereby biofuel production replaces food production, causing land with high biodiversity or carbon stocks elsewhere in the world to be converted to food production to make up the shortfall. If the resulting carbon emissions from land conversion are attributed to biofuels, then total greenhouse gas emissions can be far *higher* than those of fossil fuels.

Doornbosch and Steenblik (2007) state that the sheer scale of agricultural resources involved in production means there are “permanent physical limits to the extent to which biofuels can replace fossil fuels” (p. 5).

Social Justice

Biofuels have also been linked to numerous human rights violations. Reports of slave-like conditions for workers in Brazil have come to light and reports of people dying from overwork (Nuffield Council on Bioethics 2011). There is also evidence of the forced eviction of indigenous people from their lands to make way for biofuel production as well as fears about large tracts of land being legally bought for biofuel production, making it then unavailable for local food

production in the global South – so-called land grabbing (Franco et al. 2010).

Biofuels from Non-Food Crops

While biofuels were initially proposed as an agricultural technology that could solve several issues simultaneously, they have proven to be very controversial. There have been different responses to these controversies. Many NGOs see the technology and policies that promote it as too problematic calling for biofuel targets to be ended. Others see it as an opportunity for agricultural sciences to address these issues through innovation within the university-industrial complex.

One common way forward suggested for biofuels is the production of “lignocellulosic” non-food crops such as grasses like miscanthus and switchgrass and trees such as willow and poplar. These could produce what are called “second-generation biofuels” and also be used in stationary energy applications. The sugar in non-food biomass is more difficult to access than in food biomass, making their conversion into ethanol more problematic. There are a small number of commercial applications of this technology. Other non-food crops have also been proposed, such as the oil-producing plant *jatropha* which has been grown, with limited success thus far, in the global South.

There are many perceived benefits to these feedstocks that some claim will mitigate the negative effects of first-generation biofuels. They would not divert food from the food market. In contrast to food crops, all of the plant can be used for energy resulting in higher yields of biomass/hectare. Trees are perennial and so lock more carbon into the soil than annuals; in some cases willow has been used to rehabilitate depleted soils. They are also considered to be more favorable for biodiversity and require fewer inputs. Because crops such as willow are currently used a little in energy production, some see this as an exciting and promising area for agricultural sciences. It is claimed the plants can potentially be bred to achieve higher yields and increase their suitability to certain habitats and uses, using techniques such as genetic modification. Many have also claimed that these crops could be grown on

“marginal lands” unsuitable for food production (Nuffield Council on Bioethics 2011).

There is also agricultural research underway on alternative models of bioenergy production within what might be called an agroecological framework. These also emphasize the possibility of obtaining different types of products from the land and moving towards a bio-based economy but eschew monocultural agri-industrial production. Instead the multifunctionality of a piece of land or a landscape is emphasized, and the possibility of synergies between food, animal, energy, and other types of production is explored within a low-input, often small-scale model (Harden et al. 2013). For instance, agroforestry involves allowing chickens and pigs to circulate in a willow plantation grown for bioenergy production.

Potential Ethical Issues

Work from the social sciences has highlighted potential ethical issues raised by the development of these technologies, however. Gamborg et al. (2012) point out that it is the use of *land* rather than food crops that is the ethically important issue because the use of any land for energy crops excludes the possibility of growing food on that land. Production on marginal land has often proved to result in marginal yields, and indeed the term can serve to “marginalize” the people who previously used that land and downplay their claims to it (Franco et al. 2010).

De Lattre-Gasquet et al. (2010) state that research in agricultural sciences is now responding to the issue of agricultural scarcity. This could be seen to be true of the move to lower input non-food crops. They state that the dominant ethos behind agricultural science research is currently technological and economic: “Whether they like it or not, public research institutions are being propelled to the crossroads of science and markets as a result of unprecedented hybridisation of scientific and economic rationality which leads stalwartly into a knowledge economy.” (p. 310). Thompson (2008a) states that future biofuels may continue to be viewed as a technology that is in opposition to nature and will meet resistance from the same groups who oppose industrial agriculture. Levidow and Paul view

non-food energy crops as promoting the same model of industrial agriculture as first generation: “Current R&D priorities for GM crops are designed to sustain agri-industrial monoculture systems, operating economies of scale and producing uniform products for industrial processing. R&D specifically for bioenergy aims to make crops more flexible, efficient sources of energy as a global commodity.” (2008, p. 28). Thus, large-scale production of non-food energy crops may also prove controversial.

Agricultural Coproducts

Agricultural “coproducts,” “residues,” or “wastes” are seen as another potential feedstock for second-generation biofuel production that would overcome the controversies faced by food-based biofuels (Nuffield Council on Bioethics 2011). Residues such as straw, sugarcane bagasse, and palm kernels are also currently used in the global North and South for stationary energy production. These are by-products of food production and so will not take up land of their own, as some see it, overcoming the “food versus fuel” controversy and requiring no additional inputs. Research on use of residues and coproducts could be seen to be within industrial or agroecological models, depending on the scale and other specifics. An example of industrial production is use of grain to produce animal feed and fuel within a biorefinery. The protein for the grain is extracted for feed, while the carbohydrates are used in biofuel production. Animal manure is another source for energy production: dung is burned currently in the global South for energy and can also be used in other high-tech applications such as anaerobic digestion that produce biogas.

Potential Ethical Issues

Use of coproducts presents their own ethical issues, however. Gomiero et al. (2009) question whether or not there is such a thing as “waste” in nature. Returning residues and dung to soils is essential to soil health, increasing carbon and nutrient content. Removal of these residues can result in soil degradation and erosion. The quantity of crop residues

that can be removed from soil without depleting the soil fertility is a complex question within agricultural sciences as it is dependent on many factors including the type of soil and the use of the land, making generalizations difficult. The application of post-combustion ash to the soil can return some of the nutrients, but little of the carbon. Residues also have other uses in the livestock sector for animal bedding and feed, creating potential competition with the energy sector.

Gomiero et al. (2009) point out that humans have already appropriated a huge volume of the earth's primary productivity and these resources are still limited. Karafyllis (2003) maintains that there are two views of nature at work here – nature as intrinsically productive allowing humanity to siphon off its surplus or nature as frugal, letting nothing go to waste: everything in nature is needed by nature. Some question the logic burning precious agricultural resources for energy, each time we burn plants we are burning valuable nutrients.

The idea of incorporating food and feed production within a biorefinery is based on the concept of efficiency and the need to extract maximum value from the resources at hand. Levidow and Paul (2008) raise objections to the ethos behind this step as were raised against food and non-food energy crops: it provides incentives for a shift towards large agribusiness and a strengthening of ties between industrial food and industrial fuel production. Others see this as a viable move representing the most efficient way to use scarce resources.

Summary

Non-food produce has always been an important part of agriculture. Fossil fuels came to replace many non-food applications of agricultural produce in the industrialized global North. Industrialized society's desire to move away from fossil fuel use and the need to provide the global South with a clean alternative have created more interest in non-food produce within agricultural sciences. Energy crops for biofuels have been a particularly high profile and controversial non-food output. The majority of food-based biofuels were

developed within an industrial, productivist ethos and not only incurred similar environmental impacts and issues of inequality as other industrial agriculture but also believed to compete with food production. Much current research within agricultural science focuses on the use of agricultural coproducts and non-food crops in response to these controversies. Some research is also taking place on promoting small-scale, local, and low-input agroecological models of bioenergy production, although this area is not widely researched within ethics and the social sciences.

Some are optimistic about the prospects of advanced technologies to reduce input requirements and lower and mitigate negative environmental impacts. Some are more cautious, making the point that any use of resources, whether “marginal land” or “wastes and residues,” is likely to incur some environmental or social cost. Commentators state that many of the barriers in place to reaping the supposed rewards of these technologies are structural rather than purely technological. Others who are opposed to industrial, productivist agriculture see these developments as more of the same and indeed a further consolidation of power in the hands of agribusiness. It is likely that the non-food uses of agricultural produce will expand in the future as well as work within the natural, social, and economic agricultural sciences to achieve desired outcomes and negotiate resource constraints.

Introduction

For nearly a century, governments around the world have been supporting their agricultural sectors to a degree that has few sectoral parallels. The preferred mechanism has been a subsidy, be it to bolster output prices, lessen input costs, take land out of production, or simply supplement incomes. More recently, however, agricultural subsidies have come under attack at world trade meetings, and even within poverty-focused civil society

organizations, based on arguments that invoke or at least imply ethics. Subsidies in the developed world, and especially in Europe, the United States, and Canada, distort market signals and stunt growth in the developing world by flooding markets with underpriced goods, thereby undercutting efforts by farmers in the south to sell their own produce. These subsidies, which in 2016 for all OECD countries totaled US\$228 billion (OECD 2017), not only stymie export opportunities but often result in the importation of foodstuffs into countries whose economies are largely based on agriculture.

Undoubtedly, there is merit to this claim. In particular, export subsidies, which governments provide to off-load surplus output at below-market costs, have a particularly devastating impact on farmers in the developing world, who find themselves unable to compete even within their home markets. As such, it is highly appropriate that export subsidies were targeted in the Uruguay Round of the General Agreement on Trade and Tariffs (GATT), the conclusion of which, in 1994, established the World Trade Organization.

That said, would the elimination of remaining subsidies, such as the price supports long used by the Europeans and extended under the 2014 US Farm Bill, necessarily enable increased agricultural exports to the north and thereby solve the problems of development among the world's poorest countries? Would agricultural commodity markets free of government intervention generate better market signals? Are farm subsidies truly the cause of so much suffering? This entry seeks to address this question through a historical review of agricultural subsidies in the West, including its rationales, and a critical assessment of the implications of subsidy removal.

A Brief History of Agricultural Subsidies in the West

The first calls for national scale farm support can be traced to the collapse of commodity prices following World War I. In the United States, the McNary-Haugen Plan, which aimed to raise

American farm incomes through export subsidies, was prepared and submitted to the Congress in the early 1920s. However, the bill met defeat at the urging of President Hoover who, presciently, feared that it would lead to inflation, overproduction, and oligopolistic control.

Curtailed investment in agriculture during the depression of the early 1930s brought renewed calls for government support. Some have argued that pressure from agribusiness, rather than from the farm community, advanced and secured state intervention (e.g., Benedict 1955); commodity prices were too variable for agribusiness to secure stable returns for their tractors and fertilizers. Whatever the ultimate cause, at the tail end of the depression, legislation, such as the 1933 United States Agricultural Adjustment Act and, in Canada, the 1935 Prairie Farm Rehabilitation Act and the 1934 Natural Products Marketing Act, was passed to, respectively, pay farmers to take land out of crop production and plant cover crops to prevent soil erosion and establish single-desk marketing boards such as the Canadian Wheat Board.

Food scarcities in Europe during World War II created a new and powerful rationale for agricultural support – achieving food self-sufficiency. In 1957, the Treaty of Rome established Europe's Common Agricultural Policy (CAP); its goals, as articulated in Article 39(1), were to increase agricultural productivity; ensure a fair standard of living for farmers; stabilize markets; and ensure the food supply and fair consumer prices.

In the United States in the 1950s, the challenge was not too little food, but too much. Support payments were espoused to deal with overproduction and farm income concerns, which were delivered in 1954 through United States Public Law 480. The key support mechanism was an export subsidy, which not only disposed of surplus stocks and stabilized farm incomes but also helped to develop foreign markets, gain political influence abroad, and serve humanitarian purposes. Income instability was similarly an issue in Canada, which was addressed through the Agricultural Stabilization Act (ASA) of 1958, providing support payments to producers during periods of low commodity prices. This was coupled with

below-market credit and crop insurance so that producers could invest without fear of devastation owing to weather events or price downturns. It is hardly a surprise, then, that output levels in Canada, as in the United States, expanded significantly over the ensuing decades.

By the mid- to late 1980s, excess production had become the problem of agriculture throughout the industrialized world, including in Europe. Guaranteed prices for key commodities had achieved the desired effect, but the resultant food surpluses only served to put downward pressure on market prices, thereby necessitating even greater subsidization by governments to ensure fair prices and incomes for producers. Indeed, an export subsidy war developed between the United States and the European Union with reverberations well beyond those two jurisdictions. Recognition of a “farm crisis” by the late 1980s prompted calls for reform through international cooperation. Writing at the time, Goodman (1991, p. 60) concluded: “Agriculture in advanced capitalist countries now exhibits precisely those characteristics which state regulation was intended to attenuate – market instability, low returns on capital, falling farm incomes, and farm failure.”

Agriculture’s virtual exemption from the GATT rules ended with the completion of the Uruguay Round (1986–1994). The Agreement on Agriculture opened market access (by converting import bans into tariffs, which were then reduced by an average 36%), lessened domestic and export subsidies (by 20% and 36%, respectively), and created new rules around sanitary and phytosanitary standards (SPS) to limit their use as a barrier to trade. These reforms, and those that have followed, have been celebrated by governments in the Global South and poverty activists as critical steps to leveling the international trade playing field. Might further reform be possible? Might agricultural subsidies become unnecessary or at least unjustifiable?

Why Subsidize Agriculture?

As exemplified by conditions in Europe through the first half of the last century, insufficient food supply relative to demand had long justified

government intervention in commercial agriculture; Robinson (1989) labels this the “food problem.” In their desire to secure reliable, safe, and inexpensive food supplies for their populations, governments have provided subsidies on key inputs like fertilizers, offered below-market-value credit and insurance, and offered guaranteed prices for commodities that might never be sold in competitive markets.

More commonly, governments have subsidized agriculture because of the “farm problem,” which is primarily the problem of instability, be it of prices, a farmer’s output level, or income. This instability derives from a number of sources. First and foremost, the biological basis of agriculture, with its dependence on variable climatic conditions and its lengthy production cycle, leads to variable output levels and therefore unstable returns. This supply variability combines with generally inelastic demand for most agricultural output to create a second source of instability – price variability. That is, a supply-induced change in price creates a less than proportionate change in demand. From the perspective of the producer, this means that a small change in aggregate supply (typically upwards as a result of technology adoption) produces a disproportionately large change in price (typically downwards). For example, between 1978 and 1999, the price of Western Red Spring Wheat in Canada varied from year to year, on average, by 15.7% in nominal terms and 16.5% in real terms (Bradshaw 2004). This level of price variability is significantly higher than that of markets for manufactured goods. For example, over the same period, the average change in the price of a Canadian car from the previous year was 5.1% in nominal terms and 1.9% in real terms (Statistics Canada 1999).

Another source of instability centers on market failure because of imperfect competition. Neo-classical economic price theory assumes the existence of market equilibrium in the absence of government intervention. However, that equilibrium is rarely, if ever, achieved within agricultural commodity markets due to the vastly dissimilar degrees of competition between primary producers and agribusiness. This feature of agriculture is widely understood and far from radical –

indeed, the 1969 Canadian Royal Commission on Farm Machinery reached a similar verdict with respect to the cost of tractors and replacement parts in the Canadian market place. This feature provides one further reason for the chronic tendency for unstable and generally low agricultural commodity prices. That is, the “farm problem” is more than just about instability; rather, highly inelastic demand, the slow growth of total demand, an imperfectly competitive market structure, rapid technological change leading to growing supply over time, and the tendency of resources to get fixed within the industry cause commodity prices to be highly variable and, in real terms, decline over time. Hence, governments have intervened by purchasing output, erecting tariffs on imports, or subsidizing prices and incomes. Of course, the net-effect of all this support has been to create surpluses that markets cannot absorb, leading to drastic declines in market prices and, paradoxically, further calls from producers and their representatives for government support. Is it indeed time to revisit the use of agricultural subsidies to address the “farm problem”? What might we expect from such reform?

Implications of Agricultural Subsidy Reform

As introduced earlier, a key reason why poverty activists and many political leaders have long called for agricultural subsidy reform is due to the perverse impact of subsidies on agricultural commodity markets into which producers in the Global South seek to sell their goods. While there is considerable merit to this claim, subsidy removal is no panacea. First, market access is often a separate issue to the provision of subsidies. Subsidies may be cut, but access to markets may still be limited by existing marketing channels, cultural norms, food safety standards, or, most blatantly, import duties. If unqualified access to northern markets can indeed be achieved, opportunities for enrichment may be realized for competitive producers in the developing world in the near term, but the longer-term prospects of pursuing economic development based on the export of

a limited number of unprocessed cash crops are less certain. Not only are such commodities prone to wild price fluctuations, but, again, over time they tend to deflate in value relative to manufactured goods. These declining terms of trade can severely limit long-term wealth generation, especially when coupled with challenges facing southern producers around access to land, capital, technology, and value-added opportunities. Of course, the export of cash crops also has implications for food security given that, where cash crops such as coffee replace food crops such as cassava, local food supplies become less reliable. This is especially troubling where farming of food crops on prime agricultural lands is displaced by cash crop production for foreign markets, thereby relegating subsistence production to marginal lands.

Even in the Global North, the fate of farmers selling into markets free of government intervention is uncertain. Though the “farm problem” can be exacerbated by government supports, these supports are not its cause. Over time, productivity gains have been achieved irrespective of government intervention, and this has largely contributed to declining prices. As intimated above, a vicious cycle exists; in export-oriented sectors in particular, farmers have internalized the need to increase production in order to combat highly variable and, over the long term, declining prices for their goods. Expansion is required for success, yet this expansion adds to depreciating prices. Hardcore free-marketers argue that, in the absence of government interference, a state of equilibrium will eventually be achieved in the market place and the industry, but this belies the historical realities of commercial agriculture (see Fraser 1992; Bradshaw 2004).

In addition to these market troubles, farmers deal with numerous inevitable risks of production, such as droughts and diseases. Some analysts suggest that subsidies that buffer these risks only hinder adaptation efforts, and there is certainly some truth to this. However, there may also be limits to such individual efforts, and in many cases, public support may be necessary to cover initial losses and kick-start adaptation. This is one of the great lessons from the Dust Bowl days on

the prairies. It was support from government that first enabled farmers to plant trees and thereby secure the topsoil. This event taught the Canadian public that it has a vested interest in agricultural lands and can play a financial part in supporting good stewardship. For these and other reasons, certain farm subsidies can play a useful role in stabilizing food production systems. The key is to find a means of supporting producers without distorting markets; this requires that programs provide income supports rather than price supports, as exemplified by Canada's Net Income Stabilization Account (NISA) program. In short, though considerable evidence reveals problematic unintended consequences of agricultural subsidies, it is, perhaps, naïve to imagine that their removal will solve the longstanding problems of commercial agriculture.

Introduction

The colonial era, typically defined as the period between the late fifteenth to nineteenth centuries, ushered in a period of European political, social, cultural, and economic domination of other territories and peoples. Colonialism was an economic prescription, a set course of augmenting European profits and markets through the extraction of natural resources (such as food, rubber, minerals, and lumber) and people (through slavery and indentured servitude) from colonized regions. European colonialism was unique from other periods of state-level imperialism and expansion because of its two-pronged model of political-economic and religious conversion efforts. Agriculture was a central component of colonialism all over the world, not only as a subsistence pattern, but also as imposed beliefs and practices that generated profound social, political, and cultural changes for both colonizers and colonized. Under colonial rule, plantation economies were established to produce goods for export such as

cocoa, sugar, tea, and coffee, as well as to feed the growing population of mining communities. Commodity crops not only modified people's expectations and tastes, but also changed people's working and living conditions both in the metropole and in the periphery. In these contexts, colonial-era social relations were built upon strict rules of intercultural engagement which consequently re-created racial and gender hierarchies in the colonies that reproduced European racial superiority and patriarchy.

Colonial-era agriculture created a capitalist system of dependence between colonizers and colonized that persists to the present day. Dupuy (1976, p. 7) notes that:

From the beginning the colonies were designed to provide the emerging capitalist countries of Europe with the precious metals, gold and silver, and with the raw materials and agricultural products needed to finance and facilitate the development of manufactures and later of capitalist industries in the centers of Europe. Consequently, the traditional economies of the various societies of the New World which were colonized, were transformed from the outside to meet the needs of the metropolitan ruling classes, at the expense of the subjugated peoples. The further growth of the productive forces of the colonies (of the native peoples) were thereby stifled, and the relationships of exploitation between the metropole, Europe, and the periphery, the colonies, were established. With this transformation, the pre-conditions for the underdevelopment of the colonies (later neo-colonies) had been met.

The “pre-conditions for the underdevelopment” in the colonies have manifested in the present as unequal multinational agribusiness practices between developed and developing nations, neo-colonial international trade agreements, and contemporary global patterns of wealth and poverty. To dismantle these patterns, worldwide social movement food activists work toward replacing and restructuring international agriculture with a system of local, sustainable, and fair practices in which farmers can afford to feed themselves.

History and Development of Agriculture in the Colonial Era

Around the world, agriculture has been the cornerstone of state-level empire building, even

predating European expansion, because of the increased need for more calories and the higher yields resulting from intensive plant domestication. For example, in the New World, food distribution was made an integral part of Inca empire-building. Murra's work (1980) on the Andean "vertical archipelago" illustrated the complex web of socio-economic relations created between different ecological zones in the empire – the high mountain Andean regions, inter-montaine temperate valleys, and the lowland Amazonian plains. Inca expansion was predicated upon a system of *corvée* labor called *mit'a* in Quechua. Households were required to labor in state fields for part of the year, and colonies of workers migrating from one region to another from different ecological zones facilitated the redistribution of food production from host zones to home zones. Chili peppers and tropical fruits from the lowlands; temperate crops from the inter-montaine valleys; and quinoa, jerked meats, and *ch'uños* (a kind of freeze-dried potatoes) from the highland communities were shipped to colonies in other regions to ensure a consistent and variable food supply. Furthermore, Inca centralized governance included investments in infrastructure, such as building a vast network of roadways and food storage facilities throughout the empire to expedite food to areas of need. Conquered communities were expected to tithe whatever food they produced to be stored for these purposes. These practices were part of an important strategy to create solidarity and minimize uprisings within the empire, so much so that it was appropriated to varying degrees under the Spanish colonial administration of the Andes (Spaulding 1984).

Earlier models of empire-building, like the Inca, often allowed communities to maintain their own subsistence patterns and other cultural distinctions. However, European colonialism was based upon changing modes of production, which included modifications to land tenure, social relations, and forms of subsistence (Bodley 2012). Under British, French, Spanish, American, Portuguese, Danish, Dutch, Russian, Belgian, German, and Italian administration, colonialism primarily took two forms: direct colonialism in which European settlers and/or administrators inhabited

colonies and maintained a physical presence; and indirect colonialism in which political and economic control was maintained by colonized people and groups who were selected to do the bidding of absent colonizers (Bodley 2012). Specific colonial-era practices within these forms varied throughout the world, based upon the country of origin of the colonizers and those who they colonized. But no matter which pattern of colonial administration, the transition to agricultural production was not viewed as a way of improving the quality of life for colonized peoples, nor was it used to unite the expansion of the empire. In fact,

[t]o the colonizers of Africa, Asia, and Latin America, agriculture became merely a means to extract wealth – much as gold from a mine – on behalf of the colonizing power. Agriculture was no longer seen as a source of food for the local population, nor even as their livelihood.... The colonized society's agriculture was only a subdivision of the agricultural system of the metropolitan country. (Lappé and Collins 1977)

Agriculture's role in colonialism around the world was part of an economic prescription, a common set of beliefs and practices used to expand markets for goods and to increase access to raw materials and labor that augmented European profits at the expense of colonized peoples and environments.

Colonial-era agriculture was organized around export-oriented, cash-crop production, ushering in centuries of plantation economies to export commodity products such as sugar, coffee, chocolate, tea, and cotton. In fact, very few of the cash crops the colonies produced were native to these regions, and one effect of the colonial era was an increase of the globalization of foods. For example, in the New World, the cross-Atlantic spread of foods, what is called the Columbian Exchange, included the introduction of New World items such as potatoes, tomatoes, chocolate, and pumpkins to Europe (Crosby 1972). As early as 1495, Columbus' second voyage to the Caribbean brought domesticated plants and animals to Hispaniola with the goal of instituting a system of tribute and putting local Taínos to work by producing foods, such as citrus, sugar, and spices, in Spanish settlements. But within 50 years (1493–1548), the indigenous population in

Hispaniola was decimated. Due to overwork, disease, and starvation, indigenous labor that the Spanish came to depend on had diminished from about 200,000 to approximately 500 people (Dupuy 1976). African slaves replaced indigenous labor, and most slaves were brought to the island, not born there, because working conditions were just as brutal as it had been for indigenous Taínos. Slavery became the economic engine of the plantation economy throughout the New World, from the southeastern United States to Brazil. One particular plant – sugar cane – came to dominate agricultural production in the New World to such an extent that scholars distinguish it using superlatives such as the “sugar revolution” (Higman 2011) and “King Sugar” (Galeano 1971). Agricultural products like sugar were exported to the northeastern United States and Europe for the production of higher-priced goods, such as rum, and these profits were used to expand the slave trade. By 1767, the colony of Sainte Domingue was considered the richest colony in the world (Bell 2007), one of the primary reasons that Spain and then France fought so hard to maintain it, even at the onset of the slave revolts that led to Haitian independence (1791–1804).

Overall, agriculture was a key component in colonialism, not only as part of the economic prescription to increase European profits, but also to increase yields for local consumption to maintain populations of workers in other colonial industries, such as mining. For example, agricultural production in Cochabamba, known as the breadbasket of Bolivia, sustained the nearby mining community of Potosí, one of the largest silver mines in the world with a population greater than London and Paris at the height of colonial production (Larson 1998; Galeano 1971). Regardless of whether colonial-era food production was intended for export or to feed the local population, the advent of the plantation economy throughout the era of European expansion shifted traditional land-holding practices, people’s intra- and inter-group identities, as well as people’s access to varieties of foods. Colonial agriculture, therefore, contributed to the modification of people’s relationships with the land and work and produced simultaneous shifts in social organization to fulfill

economic obligations within the family, society, and the workplace.

Agriculture and Shifting Social Relations in the Colonial Era

Around the globe, the colonial transition to export agriculture involved taking control of people and lands in Australia, Africa, Asia, the Americas, and Eastern Europe and claiming them to honor the supporting crown. While precolonial systems of land tenure usually recognized kin groups and/or community ownership as the primary basis for land use and inheritance patterns (e.g., Dupuy 1976), colonial officials failed to legally recognize indigenous communal land ownership. Instead, colonizers were entrusted with legal rights to the labor of conquered peoples, through slavery or servitude, and often the land itself. Plantations typically usurped the majority of arable land and were the only source of much-needed infrastructure such as roads to get goods to market, irrigation, and credit to provision fields. In many New World colonies, such as Mexico, Bolivia, Haiti, and Peru, the Spanish crown developed *encomiendas*, a land-grant system codified in the early mid-1500s with the passage of both the Law of Burgos and the New Laws, permitting colonists the right to indigenous labor and setting guidelines for patronal custody, such as building churches and baptizing indigenous people (e.g., Klein 2012). While communities were allowed in theory to maintain political control on *encomiendas*, social engagement between colonized and colonizers in practice was often akin to slavery. Even after the repeal of the *encomienda* system, the practice of concentrating landholdings and labor was maintained on haciendas, in which laborers were employed by private owners (*hacendados*). In the era of independence, haciendas became important sites of social unrest when peasant farmers demanded agrarian reform to break up concentrations of land and transfer land titles to the peasant farmers who worked it.

Colonial-era agricultural practices modified traditional systems of social relations, both between men and women as well as between

colonizers and colonized. In colonial Peru, for example, Silverblatt (1987) shows that gender complementarity and parallel descent within the Inca Empire allowed women to inherit lands and resources through their mothers' line, and men to inherit from their fathers. Women were also exempted from the tribute labor (*mit'a*) that men were required to complete. However, under the Spanish, women's right to inherit was abolished and to achieve economic goals, women were forced to provide tribute, one of the chief complaints of colonial adversaries, such as Guaman Poma de Ayala, an indigenous opponent of the Spanish colonial system (Silverblatt 1987, p. 129). Furthermore, colonial practices in Peru, as was typical under colonial administrations everywhere, also included the sexual exploitation of women. Social relations on colonial-era plantations were fraught with sexual violence, and miscegenation spurred anxiety about maintaining boundaries between groups. Those of European descent were without exception relegated to the highest caste, and those of African, Amer-Indian, and Asian descent were relegated to the lowest. However, people born of mixed race unions were classified using a social construction of identity that included characteristics such as occupation, language proficiency, and style of dress. Living in the countryside and providing manual labor on plantations were clear demarcations of lower-status racial groups. Therefore, people's position within colonial-era agriculture became an important marker for identifying ethnicity and race, as well as an indicator that guided people's behavior when interacting with people from different groups, such as plantation overseers and peasant farmers. De la Cadena (2000) demonstrates that this colonial-era racial hierarchy, particularly agriculture as a marker of ethnic identity, persisted in post-colonial Peru and has endured in various ways even to the present day.

Colonial-era agriculture had a profound role in not only modifying social relations within the colonies, but also in the metropole. Sidney Mintz's seminal work, *Sweetness and Power: The Place of Sugar in Modern History* (1986), chronicled the globalization of sugar from its production in the Caribbean to its consumption in

Europe. Sugar, indigenous to Papua New Guinea, became a staple crop diffused throughout the Caribbean colonies under British, Portuguese, French, and Spanish administration, and became a mass-produced commodity crop using slave labor. At first, sugar was consumed primarily by European aristocracy and wealthy classes in Britain. But by the mid-1600s, the price of sugar decreased, and as a result became more accessible to European poor and working classes. This coincided with the advent of the Industrial Revolution, which intensified rural to urban migration to provide labor in the burgeoning manufacturing sector. Sugar consumption in Europe provided more calories using less intensive cooking and preparation methods, such as preserving fruits as jam and drinking tea with sugar, rather than other labor-intensive staple foods, such as steel-cut oats, butter, and drinking milk (which were also much harder to come by in urban cities than they were on rural farms). Increased sugar consumption among the working classes in Europe generated profound cultural changes. Women's participation in manufacturing soared to increase company profits because they were paid less than men. Feeding the family with less time-consuming foods processed and prepared with sugar, in part, smoothed this transition to a feminized labor force.

Legacies of Colonialism in Present-Day Agricultural Practices

Colonialism throughout the world has had lasting consequences on land management practices, relations between different social groups, and forms of subsistence. In fact, colonial-era extraction of raw materials and forced labor practices (such as slavery and servitude), with the goal of increasing profits and markets, are at the root of contemporary patterns of wealth and poverty, what Dupuy (1976) refers to as "origins of underdevelopment." Lappé and Collins (1977) reveal that colonizing nations of the past are today's developed countries, and those who were exploited for their raw materials and people are today's poorest nations. Other researchers confirm

that contemporary neocolonial agricultural policies and practices maintain and reproduce colonial-era inequalities on a global scale. For example, Pilcher (2012) elucidates the effects of free trade agreements such as the North American Free Trade Agreement (NAFTA) on Mexican corn farmers. Opening up Mexican markets to government subsidized corn grown in the USA, coupled with the elimination of subsidies on Mexican corn, not only put rural Mexican farmers out of business, but also undercut small-scale tortilla producers and further concentrated the mass-production of tortillas in the hands of only two industrial multinational corn meal producers, Maíz Industrializado and Molinas Azteca, S.A. (Maseca). As a result, subsidized corn grown in the USA can be sold more cheaply in Mexico than corn grown right down the street from Mexican corn meal and tortilla factories. And if small, family-run corn meal factories try to compete, Pilcher shows that they are “reduced to mere vendors for the multinational companies” (2012, p. 403). NAFTA, therefore, drives down wages and profits for Mexican industrial and agricultural workers and small companies. In response to the relevant question posed by Moore Lappé and Collins (1977), “why can’t people feed themselves?” Pilcher shows that so-called “free trade” policies, such as forcing Mexicans to eliminate agricultural subsidies while the US Farm Bill maintains subsidies for their own corn farmers, reproduce colonial-era practices in which developed countries enrich themselves at the expense of poor countries.

Contemporary food activists and organizations shed light on the effects of neocolonial policies on industrial agriculture and attempt to build solidarity among small-scale, local, peasant farmers around the globe. One example of a locally run organization is the Pirwa in Bolivia, a cooperative work-for-food program managed by area farmers to increase food security and solidarity in a community of migrant workers (Hippert 2013). The Pirwa (which means “silo” in Quechua) operates a communal workgroup in which members farm communally held lands and equally distribute the harvest among its members. Moreover, using profits from the sale of some of the Pirwa produce,

the Pirwa provides members with staple food rations (including cooking oil, flour, sugar, and rice) after a required number of completed work-days, freeing up members to use the very little cash they earn as subsistence farmers and day laborers on higher-priced items, such as meat. Using Andean concepts of community work and balanced reciprocity, or *ayni*, the Pirwa attempts to eliminate hunger by fostering community solidarity. Moreover, the program helps to revalorize farming as a productive, respectable subsistence pattern – an important benefit to mitigate the alarming out-migration rates as area children leave and try their hand at working as day laborers in the nearby city.

Activists are also working on a global scale to undermine the effects of industrial agriculture. La Via Campesina (the Peasant Way, in Spanish) is an international organization dedicated to defending “peasant agriculture for food sovereignty as a way to promote social justice and dignity and strongly opposes corporate driven agriculture that destroys social relations and nature” (La Via Campesina n.d.). The organization uses a variety of strategies to raise awareness of the benefits of small-scale agriculture and the dangers of transnational agribusinesses and free trade agricultural policies. Via Campesina leads protest marches at international summits of the World Trade Organization and engages in international campaigns for agrarian reform to distribute lands into the hands of local peasant farmers instead of multinational corporations. Since 1993, the organization has given a voice to peasant farmers’ demands for food sovereignty and more control over their own local food systems.

Conclusion

Around the world, agriculture was a central feature in the colonial era. The transition to colonial agriculture – commodity crops grown for export – benefited colonizing nations more than those who were colonized, and profoundly shifted the way people worked, ate, and interacted with others, both in the colonies and the metropole. Key facets of colonial-era agriculture were forced

consolidation of land-holdings, slavery and servitude, and the increased globalization of foods, all of which modified people's access to different varieties of food, altered people's subsistence patterns, and entwined peasant farmers into the global capitalist economy. Present-day patterns of wealth and poverty originated in colonial agriculture. Many of the practices and effects of colonial-era agriculture live on in the present under the guise of global industrial agricultural practices and policies. But food activists, using educational campaigns and alternative farming and trade strategies, have fought to undermine neocolonial industrial agriculture to gain more control over their own food production, distribution, and consumption through international networks of organizations and social movements.

Introduction

Agriculture has been at the heart of the human ethical systems since 9000 BCE when plants and animals were first domesticated. The “invention” of agriculture meant that humans changed the way they looked at land, food, sharing, home life, family, gender, age, technology, and property.

Such massive changes have happened twice in human history. The first change was after 9000 BCE when hunter-gatherers settled down in farms in different parts of the world. New ethical systems emerging included new systems of social stratification, rural and urban, and professions. Many of these relations were rooted in ties of personal loyalty and fealty between unequal people. Such systems even included large agricultural empires like those of Rome, China, and the Maya. These systems were often “feudal” in nature, because personal loyalties were at the heart of social interaction. In these worlds, agricultural production and food were central to the meaning of social life even though farm families were often poor and oppressed.

However, beginning about 1500 CE, new ways of organizing food production using globe straddling agricultural markets emerged. For this to work, though, new ethics about the production and sharing of food emerged. Most importantly, food became a commodity in the market, just like any other. Food, land, and labor became exchangeable for cash in a marketplace where economic advantage was more important than personal loyalty. Food was also the same as any other commodity and could be bought and sold at market prices. This is the globalized market system, which continues to extend its tentacles into remote farming areas, even in recent years.

From the Beginning

In the beginning, all humans were hunter-gatherers. Humans subsisted by following food sources – whether they were seals in the Arctic tundra, ripening berries and herds of deer in the temperate regions, fish that runs along rivers and

coasts, roots dug in the desert, or the animals and fruits of the tropical forests.

Such subsistence strategies required extensive territories to support a family or clan that moved frequently. As a result the land supported very few people per square kilometer. This is because little of the natural biomass is suitable for human consumption in the form of fruits, vegetables, fish, grains, or game. Even in the tropical forests with their towering tree canopies, much of the biomass was woody or leafy and unfit for human consumption.

With such an irregular food supply, there were times of hunger and of feast. For example, the felling of a large animal, fish run, or even a termite swarm could mean that a clan ate well for a few days before the meat spoiled or was stolen by scavenging animals. But this feast could be followed by days or even weeks of food shortage when the band might eat little. A particular type of ethical structure emerged which reflected this type of subsistence. In such societies, there is little wealth and hierarchy, and the basic unit is the clan of at most a few tens or a hundred people who shared food and worshipped a symbolic god or “totem.” Such societies were relatively egalitarian, and the only type of social stratification was that of age and gender, in which the surviving older men would receive some deference – though they still needed to walk with everyone else (Collins 1992, pp. 47–48).

Frequent movement also meant that people owned only what they carried. Strangers were rarely encountered and often perceived as potential threats. There was no fixed place of residence – rather there was a territory in which the band or clan wandered. Most important from a latter-day perspective, there was no way to store food, and what was collected, hunted, or caught was consumed quickly. The one domesticated animal the wandering bands had was the dog, which warned the group of approaching nocturnal predators (including at times other humans) and was also helpful with hunting. Constructed shelters were temporary and typically used for a few days or weeks.

Women in such bands had on average 4–5 children in a lifetime, and life expectancy among hunter-gatherers was typically pretty

short – perhaps 20–25 years, largely as a result of the frequent deaths of infants, small children, and older adults during the stressful times when food was scarce. An injury also meant that if a person could not walk, they would likely die – anyone older than an infant who could not walk with the group to the next food source risked abandonment.

The First Great Transformation

About 9000 BCE a few of the wandering humans began to settle down into small villages, cultivate grains, and domesticate animals. They did this first in the Middle East, though other areas of the world soon followed. In effect, these humans stopped following the edible crops and animals and instead developed plants which produced a great deal of food suitable for humans on land which was within walking distance of a “house.” This piece of land, instead of growing woods and leaves which humans could not eat, was cleared and covered with crop-like wheat, maize, vines, fruit trees, or other crops, which were edible by humans.

Also, beginning about 9000 BCE, the farmers domesticated animals like sheep, goats, cows, and chickens. Domestication had big advantages over hunting for humans; with hunting, humans hunt animals that hide. But with domesticated animals, the “meat” follows the humans who tend them. Slaughtering (or milking) one of the animals was much easier than chasing wild animals in the forest. The most important meat could be slaughtered when it was needed. Instead of wandering in the forest searching for animals to snare, trap, or spear, the “hunter” could simply slaughter one of the chickens when it came to roost at the farm in the evening!

In other words, farming and the domestication of plants and animals meant that the old order was reversed. Instead of searching nature for food and subsistence, humans bent nature to produce the food products they needed where they lived and no longer needed to follow the harvests that nature provided. Settling down meant that humans accumulated more goods than they could carry and in

particular meant that food supplies could be stored, eliminating the terrible hungry periods.

With such changes, new ethics framed by the nature of agriculture emerged. The most important were ideas about the ownership of food stores and other properties. For example, who had rights to ownership, who lived in a home and hamlet, and who inherited the wealth of those who died? New ethics about the unequal distribution of property and the rights and responsibilities to protect property were created too. Who would be responsible for sharing in times of famine? What did it mean to be invited to eat at a stranger’s house? How would raiding parties be organized when there was hunger and the only food available was in a neighboring field? And who would decide how to erect defenses against raiders? Finally, who was required to work in which fields and when, and what did this assistance mean for the sharing of the harvest?

A strongly gendered division of labor in which women cared for the house and children while the patriarch was the “public” face of the family also emerged in most such societies. Patriarchy emerged to assert control over the resources that the family or clan produced.

There were more implications for social life, particularly with the development of permanent housing made from local materials (e.g., mud, sticks, stone, reeds, hides, etc.). Birth rates also increased as the time between pregnancies decreased, since it was no longer necessary to carry children until they walked. Women became pregnant more often and, as a result, more focused on child rearing; a typical average birth rate was 7–8 children per woman. Finally, a simple injury was no longer necessarily fatal since a leg wound could be tended at home and the injured person fed from the ripening fields of their family, even if they did not work.

Permanent dwellings meant also that clans began living near each other and socializing with a larger group that came to be thought of as kin-based ethnic group or what is known by the archaic term “tribe.” Such groups were organized into a homesteads, hamlets, and series of hamlets. Such groups grew quickly, because of rising birth rates, and the fact that the young and elderly

survived hungry periods and simple accidents did not lead to abandonment. Older people – grandparents – became more common and honored.

It was in this first Great Transformation from a sparsely populated hunting and gathering world in which life was focused on migration to a farming world focused on the cultivation and harvest of crops that the arts, trade, law, philosophy, music, religion, and literature could be cultivated. Such new culture eventually became the basis for the wealth, power, and ethics of great agriculturally based empires like Ancient Rome, Ancient China, and Mesopotamia.

But making all this work required shifts in what was viewed as right, wrong, good, and bad, i.e., what was *moral*. To reinforce this, densely populated areas began to tie themselves together with shared cultural rituals. By about 5000 BCE, they began to create cities centered on a government. Such governments were controlled by powerful political figures such as kings and their courts and even emperors.

Ethics and Early Farming Communities

Starting about 9000 BCE, farming communities in places like Mesopotamia, the Indus River valley, China, and Egypt began emerging. Annual rituals marked planting, arrival of annual floods or rains, and harvest. These rituals reminded people of the centrality of agriculture to subsistence. Such rituals connected the group to the spirits that were often identified with the landmarks near where they lived and the animals the group respected. Supernatural forces were associated with weather because of the importance of timely rains for a good harvest. Specialists, i.e., shamans, who could divine or control the rains, became important figures. Concepts defining gift giving and trade also emerged, with personal gift giving regarded as the most honorable form of “exchange.” And a few people began to specialize – and become very good at – the tending of animals, horticulture, ritual, trade, rainmaking rituals, and even fighting.

Nevertheless the overall organization of each community was not like the complex economy of today, in which every family is dependent on the

functioning market to survive. Rather it was what the classical sociologist Emile Durkheim (1973, pp. 64–69) called “segmented.” To illustrate, when a clump of seaweed grows on the floor of the sea, each individual leaf moves together with the waves and seems very alike. But what looks one single plant is not. Any single leaf does just fine if separated out and planted elsewhere on the sea floor. In the same way, Durkheim wrote, each independent peasant household provided for itself independently of its own needs by growing its own grain, building similar housing, and wearing similar clothing.

Or as Karl Marx described the French peasantry in the nineteenth century using an even more vivid metaphor, that of a bag of potatoes:

The small peasants form a vast mass, the members of which live in similar conditions, but without entering into manifold relations with one another... The field of production, the smallholding, admits of no division of labour in its cultivation, no application of science and, therefore, no multiplicity of development, no diversity of talents, no wealth of social relationship. Each individual peasant family is almost self-sufficient... The smallholding, the peasant and his family; alongside them another smallholding, another peasant and another family. A few score of these make up a village, and a few score of villages make up a [province]. In this way, the great mass of French nation is formed... much as potatoes in a sack form a sackful of potatoes. (Quoted in Waters 2007, p. 9)

French peasantry in other words produced what it itself needed, without reference to larger markets. Families planted enough wheat for their own bread, barley for their own beer, raised their own vegetables, and tended the livestock they needed to feed their family. Little food was grown for the market.

But this was not all. Often farmers were dominated by a chief or king who sought tribute from them which might be 5–20% of their crop; so as a rule of thumb, a peasant family might plant 90% to feed themselves and then an extra 10% in order to satisfy their tribute obligations to the local nobles. In turn, the noble was responsible for “his” peasants in the event of famine, pestilence, invasion, or impoverishment. The relationship was a sentimental but unequal relationship, not one where labor was bought and sold. It was a

moral relationship that had a past, present, and future between noble families and the peasantry.

The Ethics of the Great Agrarian Empires

Daniel Chirot (2011, p. 141) calls the implicit compromise between the relatively independent peasants on the countryside and the luxury-loving elite a “terrible dilemma,” because the peasantry gave up individual freedom, in exchange for being part of a state which provides protection from invasion and famine. The dilemma was that the subsistence peasantry became ever more productive; they became attractive to raiders and brigands seeking to steal the wealth their lands and herds produced. The first response of the farmers was to band together under the leadership of a great fighter. At first, this warrior chief was only “in charge” during times of military threat. When there was no threat, he would return to his fields and be the patriarch of his own clan. But, by about 5000 BCE, a few of these villages developed into cities that supported a permanent “court” of officials. In an implicit exchange for organizing military protection, these new “nobles” required the peasantry to surrender not only the crops but the freedom to leave the “kingdom.”

The right of the king to “his” peasants was legitimated via ideologies emphasizing the divinely ordained power of the king vis-a-vis the peasantry. Thus, even though the health of the kingdom ultimately rested on the success of the low-status peasantry, ideologies emerged that insisted that the nobility was higher and more important. The kings were even considered to be deities. In this way, farmers became “tied” to the land, i.e., they were “inalienably” connected to a particular place in a manner which meant that they could not abandon their ruler but also their ruler could not expel them from their farm.

Wherever agricultural wealth accumulated, such systems of inequality between the rulers and ruled emerged. Such systems were focused by the personal loyalties of feudalism. Typically the peasantry owed the particular king’s court a share of their crops and service in his army. In exchange the feudal lord extended protection from famine and invasion specifically to the peasants for whom he inherited responsibility. Farmers

all over the world encountered this terrible dilemma in places as diverse as Ancient Mexico, Peru, China, Rome, Egypt, Mesopotamia, and the Indus River valleys. But what was lost and gained in this trade?

The peasants of course lost their freedoms to travel and criticize rulers, and the sons of the peasantry were drafted into battle. Tax loads could be heavy, too. But, this loss of liberty also protected for the peasantry from other threats, especially attack by enemies, and periodic famine. The nobility protected “their” peasantry from attack and starvation by maintaining fortresses or castles, where food was stored to distribute during famine or military siege.

Such rights and responsibilities were embedded in feudal society via ritual and religion. Rituals celebrated the connection between the peasants and their king, who was a father figure to whom the mysteries of religious faith demanded obedience. From today’s perspective, such tie seems fantastical; but they worked to tie kingdoms and even empires as large as Rome together in unequal kinship-like loyalties.

The Ecology of Feudalism: Elites and “Their” Countrysides

Historian William McNeill (1978) described well the ecological relationships of what became the great agricultural empires between about 4000 BCE and 1500 CE. What these agricultural empires had in common was that they had rich farm areas, which McNeill called the “engines” of demographic and economic growth, centered on a city.

Cities had three things essential to such empires: the court of the king or emperor, a priestly caste who controlled religion, and the markets with their traders. Unlike today, the cities were not centers of manufacturing and production, and the wealth of the kingdom came from the rural areas.

But still the nobility, priests, and traders had two problems. First, they could not produce enough food to feed their population and so relied on the existing countryside to send them the food-stuffs they needed to live and become wealthy. But there was a second problem, too, which was

that the premodern city was dirty and had high rates of disease so more people died than were born. As a result, a continual influx of new people from the countryside was needed so that the king's court, the priestly caste, and the marketplace could be staffed. The engine of growth – the settled rural areas – provided a solution to both problems. They had surplus population as a result of their high birth rates and sent food as a symbol of their obeisance.

The Ethics of Food and Agriculture in Feudalism

Food was the center of ethical life in feudalism whether sending tribute to the king, offering food to the spirits or gods, feeding a family member, or hosting honored guests. Food defined love, responsibility, and friendship. Those who were the “us” group supped together. “Come and eat, this is my grain, that I grew with my sweat, and it is given to you.” The food the farmer grew had special meaning beyond its role in nourishment – it was produced through the farmer's own work and sweat and was created because the farmer gave of himself. The sweat was turned into food, which was used to nourish children, and those who the farmer loved. Or it went to guests, who were invited to eat of the rice, maize, beans, or bread that the farmer created; guests were told to “come and eat, this food is created personally by me, and I give it to you as a mark of my respect for you.” Or perhaps, “because I have grown this (rice or maize) myself, it tastes far better than what money buys!” (Waters 2007, pp. 10–12).

In agrarian societies, the agricultural cycle of planting, tilling, and harvesting structured the year. And everywhere rituals marked shifts in the weather and cropping cycles. In the temperate zones, spring festivals signaled planting. There were also special ceremonies associated with the winter and summer solstices and especially harvest festivals. The priestly caste emerged, which claimed control over dangers that threatened the crop cycle. Songs, dances, altars, religion, and artwork were created to appease gods who controlled the weather, the harvest, crop diseases, and particularly rain cycles.

Loyalty to the group was a primary ethic in traditional horticultural societies. Work groups, military groups, occupational groups, ancestor cults, and many other types of groups were organized. Ancestors buried on the land in places like China, Africa, and Europe were important too, representing the connection between the ancestors, the land, and the future. Holy days were timed to reconstitute the group; indeed, these agriculturally derived holidays are still important rituals for extended families, even in the modern world. For example, in the modern United States and Canada, this happens during the Thanksgiving holidays. In China today, this happens in the context of the spring and fall festivals when factory workers return home.

The primary unit of loyalty in subsistence societies is the extended family, i.e., what Durkheim called the “segment” and Marx sarcastically compared to a potato in a bag. As Marx and Durkheim described, tasks were delegated within this family, and the growth (or shrinkage) of the family unit was key to the family's well-being, not the cleverness of a particular individual entrepreneur.

This also led to an ethic emphasizing that if one member of the family was fortunate and became rich or powerful, the rest of the family could call on that person to share. Modern writers sometimes call this “amoral familism” because it means that when a person does have the capacity to favor others in decisions about hiring, purchasing, and so forth, they tend to look to family first, not the “best financial deal” or the interest of a larger corporation. To call such a situation amoral or corrupt, though, belies the centrality of family loyalty in traditional agricultural communities. In such communities, ethical behavior is to serve one's own kin first and not that of a distant modern bureaucracy.

The Second Great Transformation

The first Great Transformation gave birth to the type of agricultural society described above. There were villages, extended families, nuclear families, “tribes,” feudal systems, and the agricultural empires. Relations between the nobility and

the peasantry were exploitative, but also sentimental. But then something began happening about 1500 CE in Europe to end this long era. Values and ethics shifted toward something new: Markets, money, and economic efficiency came to be a new source of both values and ethics. This of course is the world familiar to the modern readers of encyclopedias like this one; it is the world of the global marketplace in which we sell our labor to the highest bidder, in exchange for the hard cold cash needed to buy our subsistence. Or as “Ma Wilder” complained in the nostalgic *Little House on the Prairie* children’s books written by daughter-in-law Laura Ingalls Wilder:

“There’s not ‘but’ about!” Mother said. “Oh, it’s bad enough to see [our son] Royal come down to being nothing but a shopkeeper! Maybe he’ll make money, but he’ll never be the man [a farmer is]. Trucking to other people for his living, all his days. . . .

A farmer depends on himself, and the land and the weather. If you’re a farmer, you raise what you eat, you raise what you wear, and you keep warm with wood out of your own timber. You work hard, but you work as you please. You’ll be free and independent son, on a farm. (Wilder 1933, pp. 367, 370, quoted in Waters 2007, p. 5)

As Ma Wilder knows, the older ethic of family loyalty is turned on its head in the new world, and cash becomes the ethical imperative for our capacity to eat. Land and labor become “alienable” in the new world, meaning that each can be sold separately. You must become a person who values time as money and opportunity to “truckle,” rather than relationships and independence. Land becomes defined in terms of market productivity, separate from the people who may or may not live there. You come to define good in the way Benjamin Franklin did:

Remember that time is money. The man that can earn ten shillings a day by his labor, and. . . sits idle, on half of that day, though he spends but sixpence during his diversion or idleness, ought not to reckon that the only expense; he has really spent, or rather thrown away, five shillings besides. (Weber and Kalberg 2002, pp. 13–16)

So how did the ethic of cold hard impersonal cash described by Franklin become so important in the older farming world, where sentimental relationships were so central? After all, to create

this new world, the older ethics of personalism, paternalism, feudalism, and tributary payments need to disappear and be replaced by the new ethic. How did this happen?

The Rebellion of the Rich Against the Poor

The classical sociologist Karl Polanyi (1944) describes the second Great Transformation, when traditional agricultural society became the modern market economy. Polanyi describes the second Great Transformation as beginning in England in about 1500 CE, when the rural areas began to be transformed. Polanyi writes that traditional peasant farmers were changed from being decent farmers taking care of their own families to being labor, which could be bought and sold on the open market, particularly in the new industrializing cities. Polanyi calls this a “revolution” because it upended the old unequal relationship between the feudal lord and peasant and replaced it with a world where cash, labor, land, and product could be bought and sold. He blames this change on the nobility who profited when they abandoned their responsibilities to protect “their” peasants and sold the land the peasants had considered theirs since “time immemorial” to the highest bidder. Polanyi wrote about The Great Transformation, which he called the “revolution of the rich against the poor” (1944, p. 35):

The lords and nobles were upsetting the social order breaking down ancient law and custom, sometimes by means of violence, often by pressure and intimidation. . . . The fabric of society was being disrupted; desolate villages and the ruins of human dwellings testified to the fierceness with which the revolution raged, . . . wasting its towns, decimating its population, turning its overburdened soil into dust, harassing its people and turning them from decent husbandmen into a mob of [urban] beggars and thieves. (1944, p. 36)

A new type of severe urban poverty emerged in the nineteenth century from this dispossession, even as the world became richer as a result of the Industrial Revolution. Farmers who had feudal rights to farmland since “time immemorial” were pushed off the land that produced food and into the cities where they became urban factory workers. Planting decisions were determined by the needs of the marketplace for food, raw wool,

cotton, and linen needed by the textile mills. The final word was with the price-setting commodity brokers, not the farmers.

In nineteenth-century Europe, this change often meant the land was shifted to raising sheep for the wool needed in the factories of the Industrial Revolution. In India and the southern United States, vast tracts were planted to cotton. In other places, and at other times, central governments and capitalist farmers created farms for wheat, maize, and other grains which were sold into markets and purchased by the wageworkers in the rapidly growing industrial cities. The point Polanyi made was that peasants who had had rights vis-a-vis old feudal lords in the “terrible dilemma” lost much in a world torn asunder, where the old ethics were traded for new ones. The old subsistence peasantry suffered being decent but poor farmers, but the new urban wage laborer lived or died at the whim of the industrial labor market described by writers like Polanyi (and Charles Dickens) who saw them become “a mob of beggars and thieves,” in cities like nineteenth-century London.

In feudalism, land, and the food it produced since “time immemorial,” was *inalienable* from the peasants who lived on it – meaning that feudal landlords could not kick the peasants off when they sold the land. There also was no such thing as “title.” As a result the peasants could also not sell “their” land rights nor borrow money from a bank using the land as collateral. In the older system of feudalism, the peasantry and the land were the same inalienable unit. And indeed the king might “sell” the lands (complete with peasants) to another noble, or the land might be captured in a war, but irrespective of this, the older morality of feudalism prevailed, i.e., the peasants and their heirs remained on the land, alive and producing for their own consumption and payment of tribute.

But the advent of capitalism with the separation of subsistence peasants from their farms introduced new incentives to the nobles who held legal title to the land, to move the “landless” peasants off. And indeed, this was the “Great Transformation” and “revolution of the rich against the poor” that Polanyi wrote about. For example, when cotton, flax, and wool in great

quantities were demanded at the textile mills, peasants were foreclosed on. For example, in nineteenth-century Scotland, peasant land was given to the production of single cash crops, for example, sheep for wool, flax for linen, or wheat to make the bread sold to factory workers. Similar programs that required the alienation of land from the subsistence peasants occurred around the world and, indeed, continue today in parts of Africa, Latin America, and Asia where subsistence peasantries persist (Waters 2007, pp. 155–214).

But this new ethic means that land is a commodity, which is bought and sold, and produces what the market demands, rather than what farm families need to eat during the following year. What is more, the peasants who moved into the urban labor market must rethink what work means. Is it work to independently feed you and your family? Or is it work for the generation of money? Benjamin Franklin’s ethic said that money was important for its own sake, and human labor was money as measured with a stopwatch. Labor no longer meant producing personally to feed family, neighbors, nobility, or guests either. It meant truckling to other people to make a living – and as much cash as possible. “Subsistence” means buying food from the box or bin of a middleman who does not grow anything, but squeezes profit out of what others produced by “truckling” to other people rather than laboring in the earth, that most honorable of profession!

Thus, the new ethical system emerging after 1500 CE in Europe assumed that land, labor, capital, and commodity were bought and sold in the open marketplace for cash. A “spirit of capitalism” emerged, and food became only one element in a global economy, in which farms were simply capitalist factories in the field.

Watching this transformation in 1787, Thomas Jefferson framed this term in explicitly moral terms:

Those who labour in the earth are the chosen people of God. . . .Corruption of morals in the mass of cultivators is a phenomenon of which no age nor nation has furnished an example. [Corruption of morals] is the mark set on those, who. . . .depend . . .on the casualties and caprice of customers. . . . (Jefferson 1787, pp. 164–165 quoted in Waters 2007, p. 4)

Most importantly, farming and all other economic activity were no longer like that uncomplicated seaweed growing on the floor of the sea, or a bag of potatoes, but a finely tuned watch in which many elements were key. As for the old nobility, the new markets asked them to remove the peasantry from the land so it could be put to the most efficient economic use. They did this through evictions and foreclosure using bankers, the sheriff, and the army. In the process the old nobility and their capitalist successors no longer saw itself as benevolent patriarchal figures, but as hard-nosed businessmen for whom time, land, and production were cash. Former nobles came to see themselves as plantation owners with an interest in squeezing capitalist profit out of their investment in the land and labor.

So the new ethic is the marketplace Jefferson and Ma Wilder disdained as immoral. Food is no longer seen as the stuff of life, and farms sell their entire crop to a local grain or cotton dealer. Food is just another commodity, interchangeable with any other. This is fundamentally different from the older subsistence ethic, which valued food production on a farm above all others and in which food was assumed to be essential to social, psychological, and physiological sustenance.

The American writer Mark Twain described this change in ethical outlook most succinctly, when he described his protagonist Huckleberry Finn, the ne'er do well son of the town drunk, in the following way:

Huck was always willing to take a hand in any enterprise that offered entertainment and required no capital, for he had a troublesome superabundance of that sort of time which is not money. (Mark Twain, *The Adventures of Tom Sawyer*)

The Emergence of the Modern Capitalist Middle Class

But this complex marketplace also permitted the emergence of the middle class which seeks its meals not from hunting and gathering, as did all of our remote ancestors before about 9000 BCE, or by farming as our more recent ancestors did until recently, but from the vast global marketplace. People still need food, but few grow much

themselves, and they instead happily “truckle” for jobs in the labor market and for food at a nearby supermarket. As Polanyi put it, the ethical transformation is as great as when a caterpillar metamorphoses into a butterfly. Farmers and consumers become reliant on the price setting undertaken at the Chicago Board of Trade, where global grain prices are set. This market system is very successful in its own way; where before about 90% of the people produced food for everyone living in countryside and city, in the modern United States, farmers make up less than 2% of the population and are able to produce enough for the other 98% to eat and even more for export into world markets.

In this vast global marketplace, almost everyone (except Huck Finn) sells his or her labor for cash, not for love of family, or even a local noble. Today's farmers grow food and receive cash back to purchase their own food from the local supermarket, just like the rest of us. In this new world the ethics of the marketplace where “time is money” dominate. This applies equally to the modern capitalist farm, the modern capitalist consumer, and the modern capitalist grocery store, which all negotiate for market advantage, rather than appealing to the romantic, agriculturally based ethics Thomas Jefferson and Ma Ingalls asserted. In this vast market system, people who are strangers to each other work and produce in a fashion which benefits and feeds a vast network of people. And again, this market has advantages: The new system is extraordinarily productive, far more than the farmers like Ma Wilder who only raised what they ate, raised what they wore, and kept wood for their own warmth, and little else.

Food, Agriculture, and the Spirit of Capitalism

The ethic of the underlying metamorphosis is the spirit of capitalism which sociologist Max Weber described in his book *The Protestant Ethic and the Spirit of Capitalism*. Weber's spirit of capitalism reflects the view that money and cash trumps all other considerations in modern

social life – particularly those of the traditional farm where there was a close personal connection between the producer of food and those who ate. Instead, time is money and vice versa – work is not about family loyalty, sentiment, or love. Ethics are about business and profit where a close connection between work and cash is mediated by the modern businessman and where spreadsheets describing cash flow drive patterns of consumption, production, and distribution. Ironically, in the new world, only a layabout like Huck Finn can anymore afford the luxury of “a superabundance of that sort of time that has no money.” In such a world, food, even with all its cultural and ritual significance, becomes just another alienable commodity. It no longer matters who produced the grain, just that it is grain, in the same way the production of a computer is just an anonymous computer. The person who grew the grain is as irrelevant to the final user, as the person who assembled an iPad.

So the modern capitalist farm is a factory in the field, with the same ethical imperative for profit-making a textile or iPad factory has. From an ethical perspective, today’s farmer is a businessman, not the romantic figure Jefferson wrote about. And yet Jefferson’s romance still holds a place in the modern imagination; food production is still often privileged with special legal protections. Such protections often draw on nostalgia for the old days when farm work was sacred and more honorable than that of a truckling shopkeeper. Ultimately such ethical reasoning is still closely connected to the personalistic and paternalistic logic of feudalism, in which the role of the food-producing farmer as the base of society is honored. In this context there are continuing political demands for agricultural crop supports supplied as cash to support vast corporate-owned “family” farms, and aid for the poor is provided in the form of “food” stamps rather than cash. This reflects an ethic drawing on nostalgia for Jefferson’s idealized farmer and the responsibilities of the king to provide succor to “his” peasants in times of food shortages and especially famine.

Thus, food aid for the poor is still protected in special ways in modern capitalist countries. For

example, in the United States, to assist the poor, the federal government issues “food stamps” in the form of ATM cards. In African refugee camps, surplus food harvested and bagged in the United States and Europe is personalized by stamping it with the flag of the donor and then shipped at great expense around the world, even when cheap food stocks are often available in nearby markets.

The special place the modern farmer plays in the popular imagination was illustrated, in a strange place, when the most popular television commercial played during the 2013 Super Bowl football game in the United States advertised a Dodge Ram pickup truck. The truck, made in the factories of Detroit, and sold for about \$30,000, was praised by having the popular broadcaster Paul Harvey read a poem in the commercial asserting “So on the Eighth Day, God Made a Farmer,” reflecting the special place that farmers have in America’s cultural imagination, even in suburbs and cities where the Super Bowl is watched. Ironically the four-door air-conditioned pickup truck was almost incidental to the commercial – which described the multitude of tasks that a subsistence farmer would do with horses, cows, fields, and machinery. The implication of the commercial was that, as Jefferson wrote, the farmer is indeed still the most exalted creature of God.

Summary

Since the Agricultural Revolution began about 9000 BCE, food and agriculture have ordered relations between human beings. This entry is about the role that farming and food plays in ordering ethical behavior, with respect to issues like loyalty, sharing of food, the allocation of land, social hierarchy, and markets. Most critically, food and agriculture help define who is the “us” of the group who will be fed and who is the “them” for whom there is no obligation to feed. This entry explains how these needs changed during the two Great Transformations of human history, i.e., the transition from hunting and gathering societies to farming communities, which began

about 9000 BCE, and the second, which began only about 500 years ago, when most humans began abandoning farms, for the modern market-oriented society of today.

Introduction

The agricultural and financial sectors have long intersected with one another in various interrelated forms. These include financing for agricultural production, financial backing for trades on agricultural commodity exchanges, as well as financial investment in agriculture-based derivatives. Within each of these forms of financial sector interaction with the agricultural sector, the roles of states and private financial investors have shifted over time. Governments have created institutions to financially support farmers, and have put in place regulations to reign in “excessive” speculation and to limit financial actors’ influence over agricultural commodity markets. In the last few decades, however, governments have removed many of the protections and institutions that supported farmers and relaxed regulations on financial actors. Today, the balance seems to rest firmly with private actors. These shifts have important implications for farmers, consumers, and the environment.

Agricultural finance refers to the provision of capital and credit and describes how farming (and to a lesser extent agribusiness) acquires, manages, and invests capital. Agricultural financing is unique because farming is unique. Farms are often small, family-sized enterprises, which are

geographically dispersed and are dependent on uncertain factors such as weather, pests, crop disease, and access to water. Private capital is reluctant to invest in farming because it is risky in comparison to other sectors such as manufacturing or services. Consequently, governments have provided financial support for farmers in the form of loans, mortgages, price supports, export trade financing, and other subsidies. The term agricultural finance is also used to describe rural financing systems, which includes new forms of financing based on risk management such as weather insurance.

Agricultural commodity marketing and trade are areas where private speculative capital has been very active both historically and today, and as a result they are contested sites. In the nineteenth century, US commodity exchanges created fungible agricultural commodities through a combination of technological innovation in grain storage and transportation, as well as market regulation (Cronon 1992). Commodity exchanges emerged from cash markets to centralize trade and facilitate commodity exports and usually depend on speculation to operate. Speculation is trade based on the prediction of price movements with the uncertain possibility of a reward. As a result, speculation is risky and trades are usually made with no intention of taking physical delivery of the commodity, but with the intention of its resale. Speculation, if excessive, can result in sharp market swings.

Agriculture-based derivatives have traditionally referred to futures, a commodity exchange contract based on the future delivery of a specific type and amount of a commodity. Futures contracts are “derived” from an underlying physical commodity. Contemporary derivatives also refer to financial products, typically sold by banks and other financial investment firms that are further removed from actual commodities and commodity trade. These financial products often track agricultural commodity prices in an index, typically alongside nonagricultural commodities such as minerals and oil. In addition, some index products also include agricultural land. Most of these financial products were developed in the wake of financial market deregulation in the 1980s–1990s,

and investment in these financial vehicles grew remarkably after 2000.

Historically, the state has played an important role in creating institutions to support agriculture and to regulate finance. The US government regulated commodity exchanges in the early twentieth century in order to reduce chances for market manipulation by private actors and restrict excessive speculation. While the activities of banks were regulated in commodity markets, legislation supporting credit unions and other cooperative endeavors were encouraged. In Europe, agrarian interests established cooperatives and credit unions to finance and support farmers. In Canada and Australia, governments established marketing boards to manage commodity trade of grains, in part to restrict the manipulation of grain markets and to provide stable prices for farmers and orderly marketing for exports.

Recent decades have seen a systematic reduction in the role of the state in performing these functions. Financial market regulation has been relaxed in the USA, while government marketing boards have been reformed and privatized in both Canada and Australia. While the vast majority of US farm credit is held by state agencies, commercial banks’ share of farm credit is increasing (Briggeman 2011). This move away from state involvement in financial aspects of the sector has had important implications for agriculture and farmers. Whereas farmers and agriculture shaped financial regulation in the past, there are indications that finance is now shaping agriculture and agricultural commodity markets. The implications of these changes include food price volatility and increased speculative activity in agricultural commodities, including land, increased farm debt, and declining farm incomes.

The increased visibility and intensification of these trends contribute to what many refer to as the “financialization of food.” Financialization generally refers to the “(I)ncreasing importance of financial markets, financial motives, financial institutions, and financial elites in the operation of the economy and its governing institutions, both at the national and international levels” (Epstein 2005, p. 3). Financialization is expanding into areas beyond traditional agricultural export

nations such as Canada, the USA, and the EU as international organizations promote “financial inclusion” in many developing countries as a tool for agricultural development and growth (Soederberg 2013). Financialization is being extended, albeit unevenly, to new global sites, and it is accompanied by new financial actors and new kinds of financial tools.

Agricultural Finance

Agricultural finance in a formal sense is a fairly recent development. There were (and are) forms of credit associated with subsistence agriculture, such as traditional moneylenders, and agricultural credit institutions such as credit unions, which arose in Europe with the commercialization of agriculture in the nineteenth century. Scientific agriculture, however, arrived with a new production system that required a more formalized means by which to provide capital for the purchase of inputs and the selling of outputs by farmers – that is, “scientific financing” (Robinson 1913). While not unheard of, in the early part of the twentieth century agricultural finance was of little interest to private banks (Wolff 1910). In the USA, there was a general concern that the banking system took money from the countryside and loaned it to “town-centered” interests (Roosevelt 1909). The state stepped in at this point to provide agricultural credit to support the industrial agriculture model and became the lender of last resort. Farmers organized to form cooperative agricultural banks backed by the state, and state-owned institutions were established. The US government enacted the Federal Farm Loan Act of 1916 and created Federal Land Banks, and the Canadian government established the Canadian Farm Loan Board in 1927. The focus of state intervention was to provide farmers with credit and to prevent farm foreclosures (Coleman and Grant 1998).

Agricultural financing continued to be supported by developed countries after the Second World War. Agricultural commodity trade expanded as exporting countries marketed grain surpluses around the globe through export financing and subsidies. Canada and Australia

supported grain-marketing boards, which guaranteed domestic farmers’ income and extended credit to importing countries. While the farmers of exporting nations benefitted from the supports, farmers in developing countries had to compete with commodities that were “dumped” (sold at below the cost of production). At the same time, many of these developing countries, as they gained independence, established state marketing boards that followed on from colonial marketing agencies (Laan 1987; Bates 2005).

Government backed institutions to support agriculture dominated in the late nineteenth and early twentieth centuries, but these supports became politically unpopular in many countries in the wake of free trade and structural adjustment programs in the late twentieth century. By the 1970s, it was no longer seen to be in the public interest for governments to support and bear agricultural risk. The structural adjustment programs and free trade agreements of the 1980s and 1990s delegitimized state institutions by describing them as inefficient, anticompetitive, and too expensive (Bello and Baviera 2009). In a number of OECD countries, private financial institutions, along with representatives from finance ministries and large agricultural producers, began to influence agricultural policy and reorient it toward market liberalization, including pressure to liberalize state credit agencies (Coleman and Grant 1998). For example, in Canada, the crown corporation Farm Credit Canada was restructured to align with private credit in the 1980s and began to extend credit to agribusiness and processors. A similar pattern occurred in Brazil, where structural reforms in the early 1990s displaced domestic credit agencies and encouraged foreign direct investment by agri-food corporations (Kumar and World Bank 2005).

As a result of these changes, agricultural credit shifted from being primarily state supported to coming from the private domain, and increasingly from global capital (Coleman 2004). In the USA, state-supported agricultural credit has been declining and private financing is increasing. The farm credit system holds a significant amount of debt, but since the 1990s private credit has been increasingly funding farm operations (Briggeman

2011). In addition, new sources of credit are being offered to farmers, for example, machinery suppliers are providing loans and grain corporations are providing loans and forward contracts to secure supplies.

While private financial institutions and actors are providing credit to farmers in OECD countries, there has been less success in low-income countries. Economists have long linked access to credit with the adoption of agricultural technology and innovation. In addition, some economists have highlighted how the lack of agricultural finance re-enforces “poverty traps” and as such advocate for risk-based finance programs (Sachs et al. 2004; Barnett et al. 2008). As a result, international development agencies and banks have developed a number of programs to encourage private finance to support agriculture and boost “financial inclusion” (Aitken 2013). These projects include structured trade and value chain financing (Miller 2011; McMichael 2013), programs to encourage the reform of collateral laws and land titling (World Bank 2012), and micro-finance (Aitken 2013). Importantly, all these development programs are premised on debt (Shipton 2010).

Commodity Exchanges

The link between financial investors and trade in agricultural commodities has a long history. Futures exchanges for agricultural commodities were established as far back as the sixteenth century in Amsterdam (Stringham 2003), the eighteenth century in both London and Osaka (Schaefer 1989), and in the nineteenth century in Chicago (Cronon 1992). These markets emerged as trade in agricultural commodities spanned larger geographical distances, and there was a greater need for places of exchange for these goods. Buyers and sellers could purchase and sell contracts promising future delivery of agricultural commodities on one centralized platform and use futures contracts to hedge risks associated with the uncertainty of agricultural commodity trade. In addition to establishing delivery dates, the contracts established quality and

ownership of the agricultural commodity. By the mid-nineteenth century, the practice of commodity futures trading became widespread as agricultural trade increased.

Commodity exchanges centralize and organize markets, commercialize agriculture, and provide important services such as price information and risk protection. Furthermore, as government support has waned for agriculture, proponents of commodity exchanges state that these services can, and should, be extended to farmers. In particular, farmers who have difficulty accessing credit can use the services of commodity exchanges to manage risk and raise capital. But, commodity exchanges also have critics.

Historically, farmers and farmer organizations have been distrustful of commodity exchanges, and agrarians were the first and primary critics of large-scale markets speculation. Although many US states had outright banned futures, by the late nineteenth century the fictitious or paper trade of futures contracts had overwhelmed the physical trade of commodities in centers such as Chicago (Cowing 1957). For example, a contract would be written for a bale of cotton or a bushel of corn that had not yet been harvested, but a contract representing that corn could be traded many times over with multiple bets on price movements. Financial speculators benefitted from credit that enabled them to buy contracts with less than 10% of the value of contract.

The debate over whether commodity exchanges are necessary for agricultural commodity marketing and financing pivots on who one thinks should benefit from futures trading. Traders of grain initially developed early commodity exchanges. Participants include large grain farmers, grain elevator operators, railway companies, and food processors such as grain millers as key participants. Proponents of commodity exchanges argue that futures trading is a close representation of pure competition and helps to manage the risk associated with agricultural markets. For example, hedging can be used to manage risk and “insure” against unexpected commodity price swings. Although there have been many efforts to make commodity exchanges more attractive to smaller farmers and other agricultural

producers, only the largest producers are regularly active on the exchanges, and their activity is mediated by brokers. The utility of commodity exchanges is open for debate, and the debate often revolves around the role of the financial speculators who provide the needed capital to keep agricultural commodity trade liquid.

Agrarian movements were crucial to developing unique forms of financial regulation and legislation in the USA and Canada (Prasad 2012; Sanders 1999; Carney 2011; Winson 1992). The US Grain Futures Act of 1922 and the US Commodity Exchange Act of 1936 sought to limit manipulation. These regulations required all futures trading to take place on approved exchanges, mandated daily reporting by traders on their activities, and implemented “position limits” on financial speculators operating in these markets, which controlled the number of futures contracts they were legally allowed to hold at any time. In addition, the 1933 Glass-Steagall Act in the USA regulated banking and speculation by banks. The aim of the legislation was not to outlaw financial speculation on these markets, but rather to prevent “excessive” speculation that might result in market manipulation and sudden sharp price shifts (Clapp and Helleiner 2012). Since 1974, the Commodity Futures Trading Commission (CFTC) has been the regulatory body overseeing these regulations in the USA.

The liberalization of financial markets in the 1980s–1990s resulted in structural shifts in agricultural commodity markets. For example, the US Commodity Futures Modernization Act (CFMA), passed in 2000, brought in changes to rules that relaxed position limits and reporting rules. Commodity exchanges have also undergone significant organizational and technological changes in recent decades. Exchanges have shifted from discreet, voluntary, self-governed associations to multinational, publically traded corporate models with a responsibility to shareholders and profits. The trend among the exchanges toward consolidation occurred alongside investments in new exchanges in Asia, Africa, and Eastern Europe. The new exchanges are supported and promoted by international organizations as part of development programs and as a support to farmers. In

addition, deregulation has facilitated the evolution of new financial tools and actors.

Agriculture-Based Financial Derivatives

Although tight regulations on agricultural commodity futures trade had been in place for over 50 years, the relaxation of those rules in the 1980s and 1990s enabled banks to sell new financial products linked to agricultural commodities (Ghosh 2010). The combination of relaxed position limits and the exemption of off-exchange (over-the-counter, or OTC) derivatives from reporting, in particular, fuelled the creation of new financial products that burst onto the scene without regulators being aware of their size and scope. Finance and specifically derivatives growth is increasing in emerging markets, and it is important to note that while commodity exchanges in the industrialized countries are dominated by complex commodity derivatives, developing country exchanges are dominated by agricultural contracts.

A common agriculture-based financial derivative product that banks began to sell after 2000 is known as a “commodity index fund” (CIF), typically traded OTC or off exchange. CIFs track changes in the prices of a bundle of different types of commodities as an index. The index is made up of the prices of agricultural commodities, minerals, livestock, and petroleum products. Typically, agricultural products account for around one third of the value of these indices. CIFs enable investors to gain exposure to commodity markets without being required to purchase the actual commodities on exchanges. The Standard and Poor’s Goldman Sachs Index and the Dow Jones AIG Index are two of the more popular CIF products on the market (IATP 2012; De Schutter 2010). The sale of these financial products poses real financial risks for the banks that sell them, because they must pay out to investors if prices rise. To hedge these new financial risks, the banks began to purchase commodity futures contracts on commodity exchanges – which they were able to do given the relaxation of regulations regarding position limits. The ability to enter the commodity markets in this way then enabled them gain

financially if prices rose, and thus be able to make the payments to their CIF investors.

Around this time, banks and investment houses also began to offer other kinds of financial derivative products linked to the agricultural sector (Burch and Lawrence 2009, pp. 271–272; McMichael 2012, pp. 988–991). These other products include funds that invest not just in commodities but also in farmland and shares in agriculture-based firms, often on exchanges, and referred to as exchange trade funds (ETFs). BlackRock, the world's largest manager of financial assets, for example, established its Agriculture Fund in 2007, which in 2016 managed over US\$230 million in assets invested in commodity futures, farmland, agricultural input firms, and food processing and trading companies (BlackRock 2016). General agricultural funds typically bundle these investments into an index in which retail and institutional investors can purchase shares. Some of the new agriculture funds specialize specifically in farmland acquisition, and as of 2012 some 66 funds included farmland in their investment portfolios (Buxton et al. 2012).

Large agricultural commodity trading firms have also begun to sell agriculture-based financial derivatives. The largest grain trading companies – Archer Daniels Midland, Bunge, Cargill, and Louis Dreyfus – are all heavily engaged in the agricultural derivatives market (Clapp 2015). Each of these firms has established a financial arm to manage its involvement in these markets. Commodity trading firms tend to have an information advantage in futures markets because they are often the first to know of impending crop shortages or other interruptions to agricultural trade (Meyer 2011). These firms use agricultural derivatives to hedge their own risks in the physical commodity trade, but it is difficult to discern what is hedging and what is speculation, making regulation particularly challenging (Murphy et al. 2012).

The increased activity of financial actors after the passage of the CFMA in 2000 is reflected in the growth of agriculture-based derivatives. The total assets of financial speculators in agricultural commodity markets increased from US\$65 billion in 2006 to some US\$126 billion by early 2011 (Worthy 2011, p. 13), and the number of

investment funds in food and agriculture rose from 33 in 2005 to 240 by 2014, managing some US\$45 billion in assets (Valoral 2015). Similar to the late nineteenth century, fictitious or paper trade of futures contracts has once again exceeded the physical trade of commodities. In the US wheat futures market, for example, financial speculators' share of the trade increased from 12% in the mid-1990s to 61% in 2011 (Worthy 2011, p. 13). In the international coffee market, it is estimated that 1 kg coffee is traded 8,000 times over in speculative trade (Breger Bush 2012, p. 40).

The main investors in these new agricultural commodity derivatives products are large-scale institutional investment funds that are seeking to gain exposure to commodity markets. Previously, the commodity markets in the USA restricted investment by banks, but the relaxation of banking regulations in the 1990s by the CFMA opened agricultural commodity investment and speculation to a whole new set of financial actors. Institutional investors include insurance companies, pension funds, mutual funds, hedge funds, sovereign wealth funds, and university and foundation endowments. These investment funds pool their resources, which enable them to expand and diversify their investment options while sharing transaction costs (Burch and Lawrence 2009, pp. 272–273; Clapp 2014). Large-scale investors tend to make long-term passive investment decisions that do not require active management, and do not always have detailed knowledge of their own investments. Some estimates put all agricultural investments of pension funds at around US\$320 billion in 2012, up significantly from the US\$6 billion they held in investments in this sector in 2002 (Buxton et al. 2012, p. 2). Investment in agricultural commodities fell in 2014–2015, as the sector overall saw significant price declines. However, investment in the sector began to pick up again in late 2016.

Implications of a Reduced Role for the State

Whereas the state took a strong role in providing institutions and regulation at the intersection of

the financial and agricultural sectors in the past, in recent decades we have seen private actors take a front seat in agricultural finance. Private financial investments linked to agriculture have direct consequences for physical commodity markets – production, pricing, storage, and trade – and in turn these changes have important consequences for farmers, consumers, and the environment.

Agricultural financing is increasingly being directed to agribusinesses and other “industrial” targets. At the same time, industrial farming requires an increased amount of capital to fund day-to-day operations, as well as medium-term credit for major equipment purchases and long-term credit for land purchases and development. In turn, farmers are signatories to contracts linked to companies for inputs, machinery, and lines of credit. While access to credit is said to lead to the adoption of agricultural technology and innovation, an additional implication of credit is debt. Farm debt is on the rise in Canada and the USA. Whereas some economists have suggested lack of credit leads to “poverty traps,” there are also indications that rising levels of debt are another kind of “poverty trap.” The dependence on agribusiness for inputs and financing can restrict farmers’ ability to determine farming methods independently. Instead, agricultural finance is flowing to less risky corporations and private industry, and there are indications that farmers’ indebtedness is creating opportunities for new kinds of financial partnerships (Ouma 2016; Sippel et al. 2017). Farm corporations (Magnan 2011) and large-scale land acquisitions (McMichael 2012) are linked directly to international capital and markets. The volatility of those markets is making it very difficult for independent farmers to operate without new financial partners.

The financialization in the food system has also been widely considered to be a factor in volatile commodity prices, as food and agriculture prices tend to react and follow trends in financial markets. As more money was invested in commodities after 2000, food prices began to climb rapidly. In the 2006–2008 period, average world prices for rice rose by 217%, wheat by 136%, maize by 125%, and soybeans by 107% (Kearney et al. 2008). Although some analysts see no link

between rising financial speculation and food prices (Irwin and Sanders 2011), others are concerned that speculation rather than supply and demand is shaping prices (IATP 2012). There is now growing recognition among international organizations that speculation in agricultural commodity markets exacerbates price trends. The Bank for International Settlements noted, for example, that financialization influences commodity prices, especially in the short term (2011). Several UN reports have also come to a similar conclusion (De Schutter 2010; UNCTAD 2011). This volatility has important implications for consumers, especially in developing countries that are increasingly reliant on imported foodstuffs. As food prices rose in 2007–2008 and again in 2010–2012, hunger and social unrest became key concerns for governments.

Financialization in the agricultural sector has also been associated with the global land rush. Financial investors have been identified as major actors in the rise in large-scale agricultural land acquisitions (McMichael 2012; Fairbairn 2014). Paradoxically, financialization has made investments in agricultural production appear to be both more secure than financial investments, and provides a way to minimize risks associated with volatile agricultural commodity prices. The development of new financial instruments has also made the involvement of financial investors in land much easier. Investors can invest financially in new kinds of land-based derivatives such as land funds and land index funds without taking on the risk of owning the land directly and individually (Burch and Lawrence 2009; McMichael 2012). Instead, they acquire exposure to the productivity of the land through intermediaries such as large investment banks and hedge funds (GRAIN 2008). Investor acquisition of large tracts of land is associated with both social and ecological consequences. Smallholders are often displaced from lands that they have traditionally occupied and land is often cleared of forests for large-scale industrial production of both food and biofuel crops, which have implications for climate change, soil erosion, and biodiversity loss (White et al. 2012; Cotula 2012).

Summary

The risks associated with agriculture remain. In fact, it could be argued that with climate change the risks of agriculture have increased due to more severe and unpredictable weather events. What has changed though is that agricultural finance has shifted from state support for farmers to state support for financial actors and international capital. The dominance of financial actors in agricultural finance is expected to continue to increase as capital has become essential to modern agricultural production. In turn, this will likely only encourage further adoption of intensive agricultural practices that are reliant on chemical and petrochemical inputs rather than low-input sustainable practices.

The combination of a balanced public and private interest in agriculture provided a long period of commodity price stability during a good part of the twentieth century; however, recent price volatility has benefitted financial speculators but there is less evidence that agricultural producers have benefitted. The best that producers can hope for is to “hedge” against price swings, often at considerable costs. For smallholders, alternative financing models such as microcredit are becoming more entangled in global financial markets (Aitken 2013), and there is little evidence that agricultural derivatives are beneficial to small producers (Breger Bush 2012).

Introduction

This entry focuses on ethical issues associated with the decline and potential renewal of mid-sized farms and ranches in the USA. The “disappearing middle” was first identified in the 1980s. Contemporary attention to the dynamics of this declining farm sector is accompanied by strategies for renewing an “agriculture of the middle.” A national agriculture of the middle initiative posits a threefold approach to rebuilding the middle sector of the US farm and ranch structure through new business and marketing strategies, particularly those identified as “values-based” food supply chains, public policy changes, and research and education support.

Ethical considerations focus on five areas: (1) diversity, resilience, competition, and opportunity in agriculture; (2) fairness and equity through the supply chain; (3) consumer choice and control; (4) environmental stewardship and ecological health; and (5) rural vitality.

The Disappearing Middle of the US Farm Structure

The origin of the concern about mid-sized farms is the “disappearing middle” hypothesis which arose in the early 1980s following the release of a US Department of Agriculture (USDA) report. This report clearly delineated three categories of farms: small (gross annual sales between \$5000 and \$40,000 in 1981), large (sales over \$250,000), and medium sized (sales between \$40,000 and \$250,000). The hypothesis stated that mid-sized, full-time family farms in the USA were declining in numbers and in the percentage of total number of farms. The decline in competitiveness of medium-sized farms had many causes such as government policy, changing patterns in agriculture – especially shifts to large-scale farming based on wage labor – and global economic changes. More specifically the structural change was attributed to off-farm work and part-time farming, a decline in the impetus to hold onto family farms and an increase in the concentration and centralization of capital.

What experts found interesting at the time was the continuation of family farming despite all the elements working against it and despite the fact that classic family-type farms typically were not in the position to enjoy either the advantages of bigness or of smallness (Buttel and La Ramee 1991). Since the analysis in the 1980s was that large farms produced most of the food and were more efficient and that small farms did not need farm programs, the primary policy issue was how to help medium-sized farms. Those addressing this dilemma however, according to Strange, needed to recognize that size and scale are less important than fair competition, economic opportunity, growth and expansion, and the exercise of economic power (Strange 1988).

Farms and ranches that have historically formed the backbone of US agriculture continue to disappear. Categorized by sales (as in the 1980s), today’s disappearing farms have gross annual sales between \$2500 and \$500,000. This sector includes many “farming occupation” farms where the farm operator considers farming as his or her primary occupation. In contrast, large

family and nonfamily farms with annual sales above \$500,000 and small part-time operations with annual sales below \$2500 have increased. Figure 1 shows the national profile of these disappearing farms between 1997 and 2007.

Knowledgeable observers attribute many of the current difficulties these farms face to their increasing inability as individual enterprises to effectively compete in increasingly concentrated and globalized markets for generic agricultural commodities. For example, increased concentration in the food retail sector puts pressure on food processors to reduce their “transaction costs” by giving larger farmers market preference. It is cheaper for them to buy 10,000 hogs from one farmer than it is to buy 1000 hogs from ten farmers.

At the same time, these farms often cannot market directly to consumers because they are too large (volume of product), not suitably located geographically, or not producing products that can be directly marketed (Kirschenmann et al. 2008). Most of the farms and ranches that fall into this “market access gap” are in the \$50,000–500,000 sales category. The term “farms of the middle” will be used in this entry to describe this marketing middle. As mentioned above, historically farms of the middle have been the mainstays of the agricultural sector in many areas of the country. These farms and ranches remain important for a number of reasons. As of 2007, farms with sales between \$50,000 and \$500,000 constituted nearly 17% of all farms and generated 22% of total US farm sales. Farms of the middle are particularly important environmentally because they manage 40% of all land in farms (USDA 2009). In addition these farms and related agribusinesses provide important economic contributions to many rural and peri-urban communities and represent a key component in maintaining a diverse, decentralized, and resilient structure of agriculture (Goldschmidt 1978; Strange 1988; Walker and Salt 2006).

Renewing an Agriculture of the Middle

Recognizing the need to create strategies that support farms of the middle, farmers, academics,

Agriculture of the Middle, Fig. 1 Change in farm numbers by sales category, 1997–2007. (*All farm sales categories adjusted for inflation using the consumer price

index. Source: USDA 1997 and 2007 Census of Agriculture)

businesspersons, leaders of nonprofit organizations, and USDA employees convened a 22-member task force in 2003. The task force formulated a threefold approach to rebuilding this middle sector: (1) new business and marketing strategies, (2) public policy changes, and (3) research and education support. The following year, the task force became the national agriculture of the middle (AOTM) initiative. (For a detailed discussion of the national task force’s approach and the composition of the AOTM initiative’s coordinating committee, see the AOTM initiative’s website at <http://www.agofthemiddle.org/>.)

The founders of the AOTM initiative believed that shifts occurring in the consumption sector of the food supply chain could provide significant marketing opportunities for renewing farms of the middle. AOTM initiative participants agreed that a broad approach and new business models were needed to revitalize this declining farm sector (Lyson et al. 2008). It was decided to engage the farms-of-the-middle dilemma through a food supply chain framework. A *food supply chain* is a network of food-related business enterprises in

which food products move from production through consumption, including preproduction and post-consumption activities. Typical links in a supply chain are as follows: input suppliers, producers, processors, distributors, wholesalers, retailers, consumers, waste removal, and recycling. A *values-based food supply chain model* was adopted in which farms of the middle and other agri-food enterprises in the supply chain develop strategic business alliances based on particular values. The developers of the model drew from the business literature of other sectors such as automobile and consumer electronics. In these sectors, values-based supply chains are defined as long-term networks of partnering business enterprises working together to maximize value for the partners and end customers of a particular product or service (Stevenson and Pirog 2008). In the business literature, these long-term inter-organizational relationships are also called “strategic alliances,” “integrated value systems,” and “value-added partnerships” (Handfield and Nichols 2002).

In the agri-food arena, these supply chains (a) handle significant volumes of high-quality,

differentiated food products; (b) treat farmers as strategic partners, not as interchangeable (and exploitable) input suppliers; (c) operate effectively at regional (multistate) levels; and (d) distribute rewards equitably among the strategic partners. The model places emphasis on *both* the values associated with the food *and* on the values associated with the business relationships within the food supply chain. The chains rely on organizational structures that achieve the necessary volumes of high-quality, differentiated food by aggregating product from multiple farms or ranches and may operate at a regional rather than local or national level. Scale is achieved through collective action rather than by increasing the size of individual farms. Another important characteristic of values-based food supply chains is an emphasis on shared vision, shared information (transparency), and shared decision making among the strategic partners. These represent commitments to the welfare of all partners in the supply chain, including fair profits, fair wages, and business agreements of appropriate extended duration. Also critical is the achievement of efficient supply chain management and logistics, including product marketing, aggregation, processing, distribution, and accounting. A result is that farmers in these strategic business alliances regularly function as “price negotiators,” as distinct from “price setters” in direct marketing, and “price takers” in commodity marketing systems.

Emerging Market Opportunities

From the 1970s consumers have expressed increased interest in purchasing food that is unique and differentiated from conventional products. Products may be differentiated by attributes such as organic, grass fed, or regionally sourced (Painter 2008) or, following Europe’s lead in the concept of fair trade, by emphasizing social justice and environmental responsibility (Jafee et al. 2004). Restaurants and cafeterias of public and private institutions such as healthcare facilities, schools, universities, and corporations are particularly receptive to these types of food products, as are regional supermarkets and some national retail chains.

AOTM proponents recognize that farms of the middle have a potential comparative advantage in these emerging markets. Individual direct-marketing farms are not designed to produce the necessary volumes required for these new markets, and commodity farms are not designed to produce the necessary quality and differentiation. Farms of the middle, on the other hand, have both the capacity and flexibility to cooperate with each other and collaborate with other supply chain partners to respond to these expanding markets. In this context, the agriculture-of-the-middle strategy can best be understood as a “marketing middle” or as a third tier between direct and commodity marketing (Stevenson et al. 2011). It is important to point out that middle marketing strategies can productively involve farms and ranches that are both smaller and larger than the statistical sales range used above to define “farms of the middle.” In other words, this “marketing middle” is scale related but not scale determined.

Research and Policy

It was understood that these emerging enterprises had to be supported by relevant research and changed policies. Researchers associated with the AOTM initiative began in-depth case studies of several on-the-ground food supply chains that were testing new business and marketing models. (See the AOTM website for case studies of successful values-based food supply chains in the meat, dairy, grain, and vegetable sectors.) In summary, the research suggests (Stevenson et al. 2011) that successful values-based food supply chains are built on a foundation consisting of the three elements described earlier: (1) appropriate volumes of high-quality, differentiated products with engaging stories; (2) strategic business partnerships based on trusting, transparent relationships; and (3) effective supply chain management and logistics across the supply chain.

Researchers also discovered that to be successful, values-based food supply chains must overcome some unique challenges such as finding appropriate value chain partners; developing mechanisms for supply chain decision making, transparency, and trust; and determining appropriate strategies for pricing products based on

understanding the costs of production and other factors. They also must do what other businesses do in determining effective strategies for product differentiation, branding, and regional identity. They must acquire adequate capitalization, competent management, and effective leadership succession strategies; develop, monitor, and document consistent environmental standards throughout the supply chain; and develop effective quality control and logistical systems.

For over 10 years the research component of the AOTM initiative has been organized around a USDA-sponsored, multistate project composed of approximately 20 researchers from land-grant universities, other institutions, and research organizations. A full description of the current multistate project is available (USDA 2012), as is a high priority agriculture-of-the-middle research agenda developed through interviews of 50 researchers around the country (see Clancy and Lehrer 2010).

The need for policy change was also evident at the beginning of the AOTM initiative. Working through the National Sustainable Agriculture Coalition, language bringing attention to mid-scale farms was inserted into several USDA research and grant programs, and there has been more attention to regional farms and food systems across the Department of Agriculture.

Ethical Considerations

Ethical issues were raised about the “disappearing middle” in 1987 in a collection of essays titled “Is there a moral obligation to save the family farm?” (Comstock 1987). The greatest concerns were the loss of a way of life and an important American tradition, and the fact that many economic sectors tied to family farms would also suffer. The AOTM initiative was not begun out of ethical concerns, but rather out of market concerns. However, numerous ethical considerations have developed as the AOTM business models evolve. In addition, emerging AOTM marketing strategies manifest new paradigms that have ethical considerations.

Values-based supply chains veer from the trajectory of US agriculture along practical as well as ethical dimensions. Much of the behavior in US

agriculture since its industrialization in the twentieth century has been determined by an implicit goal – namely, maximum, efficient production for short-term economic return. The achievement of that goal was largely accomplished by pursuing three strategies: specialization, management simplification, and economies of scale. Operating by this single mandate, business enterprises (including farming) were encouraged to “externalize” related negative consequences such as, in the case of farming, soil erosion, contaminated water, and loss of biodiversity. If some unintended negative consequence resulted from the commitment to this singular goal, it was simply set aside and ignored. Consequently the predominant ethic that emerged among farmers who were forced to operate by this singular mandate was a utilitarian one – that is to “produce as much as possible, regardless of the cost” (Thompson 1995).

This approach has become increasingly dysfunctional in agriculture. Farms are biological organisms. Externalized costs ultimately can affect the biological functions of farms with negative economic results. For example, eroded soils ultimately require more fertilizer input to achieve maximum production, resulting in a negative effect on the economic performance of the farm as well as damage to the environment. Some leading economists and investment advisors have, in fact, begun to recognize the need to examine these unintended consequences. They suggest an alternative value set for the marketplace, not just in agriculture but in all aspects of the industrial economy. Porter and Kramer (2011), for example, have argued for a paradigm shift in the way business is conducted. They write that the USA has reached a point where social and environmental capitals have been degraded to an extent that they can no longer be externalized. Consequently a new kind of capitalism must now be considered, one that is based on what they call “shared value.” The “new capitalism” incorporates societal and environmental needs (not just economic needs) into its business model, where environmental and social health is integral to economic health.

Such a shared value perspective, or ethic, especially relates to agriculture in that it emphasizes improved growing techniques and seeks to

strengthen local and regional suppliers and other support institutions to increase farmers' efficiency, yields, product quality, and overall sustainability. This leads to more revenue and profits for both farmers and the companies that buy from them (Porter and Kramer 2011). In a similar vein, continuing to manage our agriculture and food system in ways that marginalize labor and raw materials in order to reap huge profits farther up the food chain is no longer sustainable (Grantham 2011). Given the depletion of essential natural resources (especially fertilizers and water), unstable climates, and the erosion of soil, it now will be essential to invest in farms, soil, and other essential resources in order to achieve successful investment returns.

Five ethical considerations are embedded in the agriculture-of-the-middle ideal. The first two are elaborated in the above text and summarized here.

Fairness and Equity Throughout the Supply Chain

The fair treatment of supply chain partners is certainly a new ethical approach to business. Values-based supply chains place emphasis on such considerations as prices based on margins above farmers' production costs and longer-term and stable contracts with producers, as well as other fairness- and equity-based transactions. Examples of these arrangements include the following: Shepard's Grain, Country Natural Beef, and Red Tomato (see AOTM website, as noted above).

Consumer Choice and Control

In the AOTM model farmers and other supply chain partners are not the only beneficiaries. Preliminary research suggests that citizens can and do reap rewards from this new approach. AOTM provides food buyers – whether the end consumer or intermediary purchaser – with additional options to act on their values. As with other food product differentiation frameworks such as organic and “local,” successful values-based supply chains provide customers and consumers with information regarding food qualities, farming practices, and business values through in-store messaging, on-farm visits, and user-friendly websites.

Three additional ethical dimensions of the agriculture-of-the-middle ideal concern the vitality and resilience of farms, communities, and the environment as elaborated here.

Diversity, Resilience, Competition, and Opportunity in Agriculture

Marketing clusters of farmers linked together based on shared values foster conditions that promote new ethical goals. First, these new clusters create economies of scale that can lessen the economic advantages of large farms over midsized farms with regard to transaction costs such as for transportation, accounting, or advertising. At the same time such clusters retain the advantage of smaller farms that have greater flexibility to adapt to changes, making them more resilient. For example, Country Natural Beef recently sought animal welfare certification because of increased consumer interest in certified meat.

As noted, concern for farms of the middle emanated from the dramatic decline in the number and vitality of these farms. While the initial impulse was largely market driven, the broader context embraced concern for the structure of agriculture as a whole. A farm structure comprised of only very large and very small farms is less diverse. Experts have shown that diversity in farm structure fosters resilience, competition, and opportunity. Farms of all sizes are needed – particularly those that can respond to the other value considerations articulated here. Finally, healthy competition by aggregations of midsize farms can offset trends toward consolidation and away from competition. As Strange (1988) suggested was necessary 25 years ago, farms of the middle can aggregate economic power to compete in the marketplace.

Environmental Stewardship and Ecological Health

The ideal AOTM farm should foster ecological resilience, although research shows no evidence at present that mid-scale farmers are more ethical than small- or large-scale producers in their approaches to stewardship and marketing (James and Hendrickson 2010; George 1991). Ecosystems are constantly changing and so the biological

functions within them, including farming, constantly change. In fact, as resilience thinkers are now pointing out, all systems – economic, social, and biological – always go through adaptive cycles (Walker and Salt 2006). Given such changing environments, adaptive management rather than control management is critical to sustainability, and midsize farms integrated into values-based supply chains may demonstrate this flexibility.

Rural Vitality

In a review of 70 years of research on farming and rural community well-being, social scientists found consistent support for the argument that midsize, family-organized farms and ranches are strongly associated with positive measures of community economic development, quality of life, civic participation, and environmental outcomes (Lobao and Stofferahn 2008). Measures of community well-being included population and employment growth, family incomes, poverty rates, quality of schools and public services, and number of churches, civic organizations, and retail establishments. These positive associations suggest that farms of the middle tend to buy and sell locally and regionally, which increases the circulation of dollars within communities and regions. They also suggest that family members of farms of the middle provide support and leadership for community-based organizations such as schools, churches, and business associations.

Trends and Challenges

This new way of doing business in agriculture, as elsewhere, may eventually create a new culture based on a “generative economy” that is dedicated to a flourishing of life for all individuals in a community, rather than an “extractive economy” which only seeks to extract as much individual wealth as possible from one’s social and ecological neighborhood. Within US agriculture there are promising trends such as the rise in interest in alternative and regional supply chains, networked systems for producers, and aggregating “food hubs” that target midsize farmers (Barham 2012). To date, most studied values-based chains

are in fact hybrids in that one or more of the partners are “conventional.” For example, Archer Daniels Midland is a milling partner in the Shepherds Grain food supply chain. This underscores the contention that developing these new models is a complex and iterative process.

There are other challenges and unsolved problems. Conventional agriculture and traditional business supply chain models are firmly entrenched. Policy tools to leverage changes that would foster favorable conditions for these new models are so far inadequate. The logistics around pulling together and sustaining successful values-based supply chains are formidable and in the early stages of development.

It is not known whether the trends described in this entry will continue on a positive or negative trajectory. New surveys will show whether the rate of decline in midsize farms has eased, whether the numbers of values-based food supply chains continues to grow, and whether the demand for these types of products will increase. Purchases of organic foods continue to rise, but only a few organic enterprises have adopted a transparent business model. Markets very likely will grow as a result of the development of food hubs. They will probably grow if more attention is paid to regional food systems which operate at a larger scale than local food systems. They are more likely to contain numbers of midsize farms that can supply larger volumes of food and support more values-based supply chains (Ruhf and Clancy 2010).

The economics of the situation are also hard to predict. In a time of high commodity prices to farmers some will leave values-based supply chains, but it is unclear what will happen when the prices inevitably drop. Energy prices may remain high enough that national and global food transport is reconsidered and more regional food supplies demanded.

Summary

There are five important ethical areas associated with the decline and potential renewal of “the middle” of the US farm structure. Renewal

prospects are based on emerging markets for significant volumes of high-quality differentiated food products for which farms of the middle appear to have a comparative advantage if organized effectively. Values-based food supply chains offer promising business strategies and organizational structures to engage these new markets. Case studies demonstrate successful values-based supply chains in the meat, dairy, grain, and vegetable sectors. Public policy changes as well as research and education are needed to support these alternative business structures. There are challenges associated with the continued growth of values-based supply chains.

Introduction

The agricultural and rural domains are characterized by internal and external drivers which menace the system, such as GM crops' threats to agriculture and human health, supermarkets' power over consumers and farmers, the imposition of the WTO liberalizing agenda, and the displacement of farmland to marginal locations due to land speculation. In addition, despite the promises of the green and biotechnology revolutions, the number of both hungry and fat people in the world is high. Meanwhile, food crises are taking place one after another, and industrial agriculture has become one of the most resource-consuming and polluting among all human activities. It is obvious that agriculture and rural policies stand on the threshold of radical reforms. This is the substrate where agroecology is growing.

Historical Background

The foundations of agroecology are well entrenched in the long history of peasant practices and discourses standing against industrial agriculture schemes. The history of opposition to industrial agriculture is as long as industrial agriculture itself. Thus, agroecology belongs to a long list of

peasant movements facing the spread of capitalist structures. Indeed, the shift from traditional agriculture to industrial agriculture can be conceived as a gradual process of penetration of the capitalist rationality into peasant social structures. This process has gone hand in hand with resistance movements. Industrial agriculture and resistance movements have coevolved. Resistance movements have tended to be stronger where conditions made the region less permeable to industrialization, such as isolation from economic centers or harsh environmental conditions. Examples of such peasant resistance are numerous: (i) the independence wars of the colonies, (ii) the Luddite revolts, (iii) the Narodnik movement, (iv) the classical movements of organic agriculture, and (v) the environmentalist movement.

- (i) Although a strengthening of capitalist structures can already be identified in Europe during the Middle Age, with a gradual reduction in the fallow period, the first movements of resistance to embryonic forms of industrial agriculture should be traced back to the decolonization wars. Incipient forms of industrial agriculture were developed during the colonization period, with initial developments implemented by the Portuguese in Madeira by the end of the fifteenth century, where they established large slaved-worked sugar cane plantations.
- (ii) The original Luddite revolt occurred in 1811. It was an action against textile factories in the United Kingdom, which were thought to be displacing craftsmen in favor of machines. The original Luddites claimed to be led by Ned Ludd. They claimed against transformations triggered by the Industrial Revolution and strongly criticized the blind adoption of mechanization and new technology. They burned factories and destroyed machines, which they understood were threatening their jobs.
- (iii) Narodism was a political movement in Russia that by mid-1800s claimed that it was not necessary to go through the capitalist industrialization to reach the socialist utopia. The Narodnik movement argued that it was

possible to achieve a solidary and equalitarian society, which would also be capable of feeding the population, through the peasant social structure and particularly building on the *obshina* – the Russian commune.

- (iv) The agrarian chemistry, initiated in 1840s by Boussingault and Liebig, in France and Germany, respectively, set the foundations of the industrial agriculture of great yields and conducted far away from cities. It was based on the promotion of chemical fertilization, on the basis of two main assumptions: (a) plant mineral nourishment is exclusively done by soil chemical substances, and (b) the damaging effects on agroecosystems caused by monocultures, of loss of nutrients, and increased vulnerability to pests can be reversed by chemical fertilizers and pesticides. In reaction, the classical movements of organic agriculture emerged in the 1920s and 1940s, basically in Europe, the United States of America, and Japan, where industrial agriculture and its unexpected consequences were more obvious. They underlined that agrarian chemistry was disregarding the importance of organic material in the nourishment of plants and thus its relevance for the agricultural practices. Liebig's chemistry was thus seen as trying to solve the problems of intensive agriculture by further intensifying agricultural activity. The classical movements of organic agriculture comprise multiple branches, all sharing similar understandings. Steiner's biodynamic agriculture, Fukuoka's natural agriculture, Mollison's permaculture, Claude Aubert's biological agriculture, and Howard's organic agriculture are some among the most well known. Their fundamental common ground is the defense of organic fertilization in view of the agrochemical dependency of industrial agriculture.
- (v) The environmentalist movement appeared in the 1960s and 1970s. In this, relevant contributions were made by (i) the publication in 1962 of Rachel Carson's *Silent Spring* denouncing that chemical pesticides – DDT

specifically – were damaging insect and bird populations beyond agriculture with unknown consequences; (ii) the 1973 oil crisis made society in general thought, for the first time, about oil shortage, and in such context Pimentel conducted his remarkable work on the energy intensity of agriculture, pointing that the energy efficiency of industrial agriculture was far lower than the one of traditional agriculture; (iii) the disenchantment with the Green Revolution, with the high-yield hybrid seeds increasing dependence on external inputs, diminishing agricultural biodiversity, and degrading the environment. The novelty was not the magnitude of environmental degradation, but the general social awareness of it. The environmentalist movements internalized the language of ecology, by means of claiming that the ecological systems, to which humankind belongs, were being damaged.

The Three Dimensions of Agroecology

Agroecology is a concept employed referring to different domains. Some see agroecology as the scientific discipline dealing with the ecological management of agrarian systems. Agroecology here thus seems to provide the theoretical basis for an organic agriculture (Altieri 1998). Similarly, Gliessman (1990) proposes to conceive agroecology as the implementation of the ecological principles to the understanding and developing of sustainable agroecosystems. Agroecosystems are the main concern of agroecology. Agroecosystems can be seen as systems of human appropriation of nature to exploit several human-valued goods and services (Toledo 1992). Agroecology, thus, should be placed, as proposed by Garrido Peña (1993), within a new emerging paradigm: the *ecological paradigm*. It is not a new discipline, but a field of research interested in the unsustainability of agroecosystems. Slightly different is the perspective of Sevilla Guzmán (1997), underlying the pluri-epistemological nature of agroecology, that is understood as an organized manner to create and

employ knowledge that accepts different forms. Sevilla Guzmán conceives agroecology as a fertile attempt to integrate social sciences and natural sciences to elaborate a strategy of development compatible with the environment. For him, agroecology is the cornerstone for designing alternative systems of agriculture, which are implemented at the production level and are being disseminated by collective social action. Agroecology, he continues, analyzes the agroecosystems and experiences aiming at examining in which cases the management leads toward adequate ways of social and ecological reproduction.

Although the foundations of agroecology should be sought close to agrarian sciences, the complexity of the domain tackled quickly triggered the widening of the focus of interest. New dimensions of agroecology have shown up, more concerned with promoting social transformations, rather than just with mere agricultural practices. Thus, according to the definitions of the mentioned above, three different dimensions of the notion of agroecology can be distinguished: (i) agroecology as the theoretical basis of organic agriculture (Altieri 1998), (ii) agroecology as the practice of favoring endogenous development for better quality of life for local communities (van der Ploeg and Long 1994), and finally (iii) agroecology as a social movement in favor of more sustainable and fairer food systems (Sevilla-Guzmán 1997).

In agroecology as the scientific basis of organic agriculture, more weight is given to technical aspects in production. Agroecology reveals the ecological management needed to achieve sustainable farming (Gliessman 1990). In agroecology as sustainable rural development, the technical standpoint goes hand in hand with a social perspective, and tackling the relationships between institutions and society becomes crucial. That is, it is assumed that the basis for the reproduction of agroecosystems rests on the local community. So, the ecological management of natural resources acquires a dimension of local development of an endogenous nature. In agroecology as a social movement, it is seen as a social endeavor fighting for environmental justice against

appropriation of communal and open-access resources by the few (Guha and Martínez-Alier 1997). Agroecology is seen as linked to ecological distribution conflicts. Here, industrial agriculture is conceived as a process of access deprivation to environmental resources and services and the endurance of disproportionate amounts of pollution by the poor. An ecological rationality is seen in these movements coming from the fact that they are struggles for the livelihood, putting the environment on a central place as source and requirement for the living.

The Notion of Agroecology

Agroecology comprises different dimensions, as shown in the previous section. However, the very notion of agroecology is highly contested. In fact, three diverse approaches to the notion of agroecology can be distinguished: (i) agroecology as the traditional peasant practices in a kind of *ecologism of the poor* (Guya and Martínez-Alier 1997); (ii) agroecology as social organizations, experiences, and discourses reexamining the modern path; and finally (iii) agroecology as the ecological modernization or sustainable intensification prescriptions in the agricultural domain to promote organic production (Fig. 1). It should be mentioned that while practitioners of the second and third notions tend to explicitly employ the term agroecology, this does not usually happen in the case of the first group. We conceive the third group as belonging to what can be termed *weak agroecology*, in the sense that under this notion agroecology does not entail a paradigm shift, but simply the undertaking of superficial amendments to conventional ways of consumption and production. This is not the case of the other two notions of agroecology, which we propose to group under the name of *strong agroecology*.

Traditional peasant practices are developed by indigenous peoples and rural dwellers in most of the marginal rural areas in the world. Experiences and discourses reexamining the adequacy for the majority of the adoption of the modern path, based on consumerism, industrial production, individualism, and technification, are well spread in

Agroecology,

Fig. 1 Notions of agroecology

Western urban centers and expressed in terms of experiences such as cooperatives of consumption and production of organic and locally produced food. Schemes of organic production based on certification standards and the substitution of inputs have also been experiencing a remarkable development worldwide in the last decades.

Conclusions

Multiple features can be identified in the present usages of the notion of agroecology that stem from past resistance movements against industrial agriculture: the concern for local identity and autonomy, like in independence wars of the colonies; the critical perception on novel technology and industrialization, like in the Luddite revolts; the resilient confidence in endogenous development strategies and the concern on social equality, like in the Narodnik movement; the centrality of organic fertilization in agricultural practices, as claimed by the classical movements of organic agriculture; and the environmental awareness and holistic perspective as in the environmentalist movement. Times are changing and the challenges agroecology faces at present are different from those encountered at other periods of history. Certainly among the most relevant nowadays is acquiring larger degrees of institutionalization.

Introduction

In its most basic form, alcohol is the product of the natural fermentation of sugars by yeast. The first time a human ate fermented berries or honey is not known. What is known is that mead, which is fermented honey, is one of the oldest alcoholic beverages. Ale and wine also made very early appearances on the beverage scene. Alcohol has been both an ingredient in the cooking and preparation of food and an accompaniment or complement to food.

Alcohol abstinence is the categorical refusal to consume alcohol as a beverage or as an ingredient in food preparation.

Sobriety is a term that people use who have changed their consumption of and relation to alcohol. Most often, the term is used by those who previously had consumed alcohol in troubling, harmful, or unhealthy ways.

People abstain or practice sobriety for a variety of reasons. The most commonly cited reasons for not drinking include concerns about the effects of alcohol on physical health, religious prescriptions against alcohol's consumption, and moral and social concerns about alcohol's effects on self and others. Alcohol is a disinhibitor. That is to say, alcohol lessens or lowers a person's inhibitions. She may find herself saying or doing things that she normally would not. It may cause her to take physical risks (health) and engage in behaviors that are regarded as sinful (religious) and that affect her character (moral) or damage her relations with others (social). While some of the reasons against the consumption of alcohol are free-standing and independent, in many cases that intertwine in complicated ways.

This entry first briefly examines the positions of five prevalent faith traditions (Islam, Hinduism, Judaism, Christianity, and Mormonism). Then the temperance and teetotaling movements that began in the early nineteenth century will be explored, highlighting the confluence of religious, moral, and scientific concerns about the consumption of alcohol. Temperance and teetotalism functioned on local and national levels. Some of the immediate- and longer-term effects of alcohol on health will be discussed. The World Health Organization has identified harmful alcohol use as a global problem. While the use of alcohol presents significant public health concerns, it is individuals who make the decision to change their relationship to alcohol. One may practice abstinence while others practice harm reduction or moderation. Some people choose sobriety, which may or may not involve abstinence. The final section explores some personal decisions individuals make about the consumption of "nonalcoholic" beverages and the use of alcohol in food preparation.

Religious Views of Alcohol Consumption

Islam

The use of alcohol and participation in gambling are two activities that are expressly prohibited in the Qur'an 5:90. In this passage, alcohol and

gaming are identified as the handiwork of Satan that will cause a person to turn away from God.

Hinduism

There is no specific ban on the consumption of alcohol in the Hindu tradition. There is, however, a large recognition that alcohol can be powerful and significantly alter one's dharma, which is the upholding of the proper order of one's self, one's place in society, and the universe as a whole. The consumption of alcohol can upset that order and balance (Dasa 2007).

Judaism

Wine is used in many Jewish rituals and holidays. Some interpreters of the Talmud argue that the "tree" of knowledge from which Eve is purported to have eaten the apple was really a grapevine. It was the consumption of this fruit that led to the fall of Adam and Eve. For Judaism, alcohol can be both used as a holy beverage and used in times as celebration. Judaism also recognizes the destructive capacity of alcohol (Posner 2009).

Christianity

Like Judaism, wine plays a particular role in religious observance. In Catholic masses, for example, the wine is taken as the blood of Jesus Christ, the son of God. In other Christian denominations such as Lutheranism, the wine is a symbol of the blood of Jesus. As is the case with Judaism, wine and other alcoholic beverages have a great capacity for destructive behavior and suffering, some of which might be deemed sinful.

Mormonism

Jesus Christ of the Latter-Day Saints, more commonly known as Mormons, believe that God gave a commandment known as the "Word of Wisdom" to Joseph Smith in 1833. In the Doctrines and Covenants 89, this commandment affirms that humans' bodies are a precious gift from God and therefore the use of tobacco, alcohol, coffee, tea, and illegal drugs is prohibited.

While some of these religious traditions have an outright ban on the consumption of alcohol and others not, there is a common thread that alcohol's consumption might bring about sinful behavior or

be very morally destructive to the individual and harmful to the social order. These concerns converged in the temperance and teetotalism movements of the nineteenth century. This is also the first time that science- or medical-based concerns are woven into religious and moral arguments against the consumption of alcohol.

The Temperance and Teetotalism Movements of the Nineteenth Century

In the early nineteenth century in England and the United States, a significant and concerted effort began to curb the consumption of alcohol. The temperance movements advocated for the use of alcohol in moderation, while the teetotalism movement advocated for all abstinence from alcohol. The word, “teetotal” has very unclear origins and there is no agreed upon etymology. Over time, the distinction between temperance and teetotalism blurred, with the demand for abstinence ringing more loudly.

Temperance and teetotalism movements were often alliances between religious groups, social reformers, politicians, and physicians. The concern was the moral and physical hazards posed by the consumption of alcoholic beverages. At this time, “drunkenness” or being a “drunkard” was seen as a fundamental moral failing of an individual; a person was seen as lacking in will power or character. In England, there was a clear concern for the rapid increase of the availability of distilled spirits and gin houses, which boasted that one could be “drunk for a penny, dead drunk for a tuppence.” The concerns often focused on the wellbeing of women and children in homes of “drunkenness.” There were also class dimensions to the concerns about drinking: while the upper classes mostly consumed alcohol in their homes, working class people tended to congregate in public places. There was also concern about the economic implications of working people being drunkards that was coupled with political and social concerns of working people as citizens (Zieger 2002).

The temperance and teetotalism movements in the United States reflect the same sort of moral,

physical, social, and political concerns about drunkenness. Drunkenness was seen as a malady of an individual but as raising grave concerns for what is now called “public health.” Public health is concerned with the wellbeing and health of communities as opposed to the health of particular individuals.

The public health concerns were so graphically and persuasively made that the movements were able to garner enough political support to succeed in the creation of a national ban on the production, distribution, sale, and transportation of alcohol from 1920 to 1933. Ratified as the 18th Amendment to the United States Constitution and commonly referred to as “Prohibition,” it was repealed in the 21st Amendment to the Constitution in 1933.

While the Amendment banned the production, distribution, transportation, and sale of alcohol, it did not ban the possession or consumption of alcohol. Enterprising individuals quickly took advantage of this in many ways. Pharmacists were allowed to prescribe whiskey for various medical ailments. The number of pharmacists tripled in the state of New York, for example, during the Prohibition era. Since wine was used in many religious services, enrollments in churches and synagogues increased dramatically.

The repeal of Prohibition was due in large part to the public health crisis that had developed as a consequence of the unregulated (and illegal) production of alcohol. On average, 1000 Americans died each year Prohibition was in effect (Okrent 2011).

The effects of alcohol’s consumption on the health of individuals and the community as a whole or social body are now the dominant way that concerns about alcohol are framed. Discussions are no longer limited to the local or national level but are happening on a global level.

Health Concerns About the Consumption of Alcohol

The Centers for Disease Control and Prevention in the United States (CDC 2012) chronicles many health concerns associated with the consumption

of alcohol. Even drinking in moderation may present risks for people in certain populations such as pregnant women, those who take certain prescription drugs, and those who have medical conditions such as diabetes. The most harmful effects follow from the excessive consumption of alcohol. Some of the effects are immediate. Since alcohol is a disinhibitor, people may engage in riskier physical and sexual behaviors that result in injury or harm to themselves or others. Alcohol poisoning is particularly dangerous; excessive consumption overwhelms the central nervous system and particularly acute cases result in death.

Certain chronic conditions can also develop over the course of longer-term consumption. The excessive consumption of alcohol over time contributes to neurological problems (stroke and dementia), psychiatric problems (anxiety and depression), liver problems, and cardiovascular problems.

The Global status report on alcohol and health published by the World Health Organization (2011) provides some of the most accurate statistics from over 100 individual country profiles. The document focuses on alcohol consumption, its consequences, and potential policy interventions on local, national, and global levels. Some of the findings include:

- The harmful use of alcohol results in the death of 2.5 million people annually;
- Nearly 4% of all deaths globally are related to alcohol. Alcohol is a factor in deaths from injury, cancer, cardiovascular disease, and cirrhosis of the liver;
- Globally, 6.2% of all male deaths are related to alcohol compared to 1.1% of women; and
- One in five men in the Russian Federation and neighboring nations dies from alcohol-related causes.

In light of these realities, the WHO recommends that certain legal, political, and economic strategies be adopted. These include greater taxation of alcohol, reducing the number of venues where alcohol can be sold, raising the age limit for buying alcohol, and greater measures for

reducing drunk driving. Additionally, the WHO recommends greater screening and assessment tools and policies for identifying individuals who are engaged in high-risk drinking and more effective treatment options for alcohol use disorders. The issue of treatment raises the questions whether alcohol abstinence is necessary for addressing the health concerns identified by the WHO and whether the goal of treatment is abstinence or sobriety.

Relationship Between Alcohol Abstinence and Sobriety

There is no standard definition of sobriety, though this word is often used in the context of Alcoholics Anonymous (AA) and other programs related to recovery for addiction. Originally founded in the United States in the 1930s, AA now has a presence in 170 countries with a membership close to two million people. The book, *Alcoholics Anonymous* (2002, 4th edition), has sold more than 30 million copies and has been translated into more than 67 languages.

In the context of AA, sobriety involves total abstinence from alcohol. That is to say, abstinence is a necessary condition for sobriety. Abstinence is a commitment to not drinking, while many see sobriety as a commitment to a way of living.

While Alcoholics Anonymous has been one of the most recognized approaches to the treatment of alcoholism and its 12-step method is the preferred protocol in both in- and outpatient treatment programs, there are competing models that suggest or allow moderate or controlled consumption. A program such as Harm Reduction for Alcohol focuses on reducing the harms that follow from problem drinking. These moderation or harm reduction programs stress behavioral changes so that one is in a better position to make informed and safe choices about their alcohol use. Many choose moderation and then may later decide to choose abstinence. With these approaches, when a person no longer drinks in harmful or troubling ways, one has achieved sobriety (Anderson et al. 2010).

Regardless of how one defines sobriety and whether total abstinence is required, sobriety is seen as a personal choice and commitment. In other words, one comes to adopt a very circumspect and proactive stance toward her consumption or nonconsumption of alcohol. A person who identifies as sober will maintain a very regulated relationship to alcohol. This is absolutely crucial for people who want to avoid a relapse. A relapse is commonly understood as consuming any alcohol when one was attempting abstinence or consuming alcohol in troubling or problem ways when one has been practicing moderation or harm reduction.

Decisions Individuals Make About “Nonalcoholic” Beverages and the Use of Alcohol in Food Preparation

For those practicing abstinence or sobriety, alcohol may seem ubiquitous and social occasions particularly vexing. It is vital that the presence of alcohol always be clearly indicated. Some people previously enjoyed the taste of alcohol and not just its effects. Others may have enjoyed the ritual of opening a bottle and pouring a glass of wine. For these people, consuming nonalcoholic beers and wines may bring them pleasure. “Non-alcoholic” in this context is containing less than 0.5% (one half of 1%) alcohol content. The choice to consume nonalcoholic beverages is personal. For some, it brings great pleasure, for some others it may trigger a desire for “the real thing,” and for some, even that very low percentage of alcohol may be seen as too much. For them, their abstinence is absolute.

Alcohol may be an important ingredient in many prepared foods. Wine and sherry are commonly used in many dishes, as are various “hard” liquors such as brandy and vodka. These alcoholic beverages are used for their complex flavors. Alcohol also appears in various extracts as well, such as vanilla. There is a common belief that alcohol “cooks off,” so that there is no alcohol content that remains.

For those faith traditions that prohibit the consumption of alcohol, this prohibition seemingly

would extend to the use of alcohol in cooking. Those who are sober and practice abstinence would also tend to avoid the use of alcohol in cooking.

Studies, however, disprove the belief that alcohol “cooks off.” The New York State Office of Alcoholism and Substance Abuse Services (2013) cites the results of United States Department of Agriculture in conjunction with two universities found even after 2.5 h of baking, 5% of alcohol remained. This is ten times higher than what is considered nonalcoholic. Given the high percentage of alcohol that remains, those who practice abstinence or sobriety may find themselves unknowing consuming alcohol. Regardless of the reasons one choose alcohol abstinence or sobriety, disclosure of alcohol as an ingredient is important.

Summary

This entry has defined alcohol abstinence and sobriety and their relationship to each other. There are various sets of reasons why a person may choose not to consume any alcohol or choose to consume in a very intentional and well-informed manner. Religious reasons often focus on the possible sinful nature of the consumption of alcohol itself or the sinful behaviors that are caused by consuming alcohol. Health concerns are immediate and long term affecting individuals and the social body. The moral and social reasons for not drinking center on the harm or damage that can be done to one’s self and her relation to others. These sets of reasons converged in the temperance and teetotalism movements of the nineteenth century, culminating in the ban on the production, distribution, transportation, and sale in the United States from 1920 to 1933. Concerns about the consumption of alcohol are now a global matter, with the World Health Organization making recommendations directed at both individuals (earlier treatment and intervention) and at the social body through increased legislation and taxation. Abstinence and sobriety are choices made by individuals, and these choices require information about the presence of alcohol as beverages

and ingredients in food preparation. A person practicing abstinence or sobriety may choose to consume nonalcoholic versions of beer and wine and use of alcohol in cooking.

Introduction

Alcoholic beverages have been positively valued for many reasons. In the following entry these positive reasons are explored within the historical context of the development of civilization. Human beings have produced and consumed alcoholic beverages ever since they changed from wandering bands of hunters and gatherers and settled down in established communities. Although alcohol can be found in the wild, it was the development of agriculture and pottery making that gave rise to the production of fermented alcoholic beverages such as mead, fruit wines, and beer. These beverages came to be valued for reasons beyond the pleasure of their taste and the effect they produced by inebriating their consumers. In antiquity they were used in religious ceremonies and valued as a medicine; they contributed to the development of social organization by encouraging trade; and they served as a kind of currency in early economies.

Later, with the invention of distillation and the spread of that technology throughout Europe in the Renaissance, distilled alcohol was initially identified as a vital life force or “spirit,” and distilled alcoholic beverages were prescribed for their medicinal value. In the nineteenth century with the invention of faster forms of transportation, the availability of a wide variety of wines and spirits promoted the values of gastronomy. In the twenty-first century, although the harmful effects of excessive alcohol consumption have been duly noted, their beneficial effects on health have also

been acknowledged, particularly the benefit of the moderate drinking of red wine. Many contemporary societies continue to value alcoholic beverages in promoting conviviality, a value which was discovered in antiquity.

Early agricultural societies in Asia, Africa, Europe, and Central and South America all invented and consumed fermented alcoholic drinks. Several fermented drinks were made by the native peoples of Central America: the Aztecs fermented *pulque* from the agave plant, and in the Yucatan the Mayans made mead, flavoring it with the bark of the balché tree. In South America, the Incas brewed a beer made from the local grain, corn. In sub-Saharan Africa, palm wine and millet-brewed beer were indigenous, and rice wine was native to China and Japan (Gately 2008, pp. 95–101). There were exceptions: aboriginal peoples in Australia and native peoples in North America did not produce and consume alcohol. There were also some societies that, for religious reasons, prohibited drinking alcoholic beverages. With the rise and spread of Islam, Middle Eastern societies that historically favored consuming alcohol turned against it. Certain religions in India also shunned alcohol.

Even societies that did allow drinking alcohol developed moral norms about when it was appropriate to consume these beverages. For example, modern Western societies made it unlawful for children to have access to alcohol. Other prohibitions arose because of the harmful effects of severe intoxication and the social disruption caused by public drunkenness. Nevertheless, alcohol was also recognized as contributing to “the good life” of people. It played a positive role in ceremonies of celebration such as wedding feasts, as well as occasions for mourning such as wakes. Sharing a “drink” was valued as a way to encourage conviviality among people, and it was even promoted as a catalyst that could spark ideas and lead to furthering intellectual pursuits. These positive social effects were noted in antiquity, and even today the cocktail party is valued as a means of bringing people together and getting them talking to each other. In the following sections of this entry, the economic, social, nutritional, medicinal, and religious values of alcohol as

they relate to human well-being will be discussed. In addition, the aesthetic values of alcoholic beverages will also be considered.

The Social and Economic Values of Beer and Wine in the Fertile Crescent

Potable alcohol or ethanol occurs naturally when the skins of ripe fruit, such as apples or grapes, break and the yeasts that form on the fruits’ skins come in contact with the ripe interior and feed on the fruit sugar. This consuming action of the yeast is called fermentation and produces alcohol and carbon dioxide. Bees and other animals ingesting this alcohol-imbued fruit would have become tipsy, as would have our early human ancestors, when they consumed these fermenting fruits. Eventually early peoples learned to gather fruits with high sugar content such as grapes, crush the fruit, and let the natural yeasts on the fruit skins convert the grape juice into wine.

With the establishment of settled communities, the rise of agriculture and the invention of pottery making and winemaking evolved as a practice in areas hospitable to grape growing. By 7000 BCE there was an established wine culture that cultivated grapes and made wine in the Zagros Mountains of Armenia and Iran (McGovern 2009, p. 82). In the next few millennia, a taste for wine from grapes spread throughout the Fertile Crescent. However, enjoying wine was an expensive taste, more so than quaffing the considerably cheaper local beer, the importance of which will be discussed below. Wine was a luxury good that was much appreciated by the wealthy and powerful, and the demand for this fermented drink led to an increase in trade throughout the region, particularly by shipping, since wine was cumbersome to transport by land.

Babylonian and Assyrian monarchs lavishly served imported wine at their royal feasts. An early Egyptian pharaoh, Scorpion I, was entombed in 3150 BCE with 700 jars of wine which were imported from distant lands at considerable expense (McGovern 2009, pp. 166–67). By the time of the pharaoh Tutankhamen, grapes were widely cultivated in Egypt, and the boy king

was buried in 1322 BCE along with his alabaster wine cup and 26 local amphorae of red and white wines, each marked with the winemaker's name and where the wine was made (Gately 2008, p. 8).

Whereas wine at first was a luxury good, the drink of the ordinary folk in the Fertile Crescent was beer. Early people had learned that cereals such as barley could be fermented to produce an alcoholic drink; however, the starch in the cereal first had to be converted into sugar, by a process known as malting. They accomplished this by first soaking the cereal grains in water until the grains started to germinate, thereby changing the starch in the grains into sugar. The germinated grains would then be dried and ground, and boiled water would be added. Natural airborne yeast eventually would have started the fermentation process and created beer, or the fermentation process might have been induced sooner by adding yeast-imbued fruit (McGovern 2009, p. 68). Technological innovations in making beer soon developed, and beer brewing became widespread throughout the Middle East by 4000 BCE (Standage 2005, p. 10).

Beer was valued in the life of early peoples for many reasons. It had a profound effect on individuals' well-being in settled communities and contributed to the development and cohesiveness of those communities. First of all, with the rise of larger settlements, finding clean drinking water became a problem, one which hunters and gatherers who were constantly on the move did not have. Beer and other alcoholic drinks were not microbially tainted, as was often the case with the water. The fermentation process would have killed off the disease-producing organisms. With its relatively low alcohol level, beer was a safe drink to consume by these early village and city dwellers. It also would have provided needed nourishment, particularly B vitamins, since communities were usually dependent on local resources for sustenance (Standage 2005, p. 21).

Second, in early Mesopotamian societies, beer drinking contributed a greater sense of community and encouraged social bonding. People drank their beer in groups from a large shared vessel. Several people each with her or his own straw or hollow reed would drink from the same vessel.

Straws were used in order to avoid the chaff and grain debris that floated on the surface of the beer. Because a group shared beer from the same container, beer drinking was a social occasion. This act of sharing a drink was a mark of social warmth and conviviality, and beer drinking promoted these values. This social beer drinking fostered a valued tradition that continues today: "having a drink" with someone is a sign of friendship, or at least it promotes the value of having people get together in a relaxed and friendly atmosphere (Standage 2005, p. 18).

Third, as Mesopotamian societies developed more sophisticated economies and undertook more complex tasks that required a large labor force, workers began to receive a "wage" that included an allotment of beer. Thus, beer was instrumental in the development of their economies. Some of the earliest written texts are Sumerian records that list the various allotments of beer given out to workers for performing different tasks (Standage 2005, p. 35). As beer drinking was a widespread and popular practice, paying people in beer was a natural form of currency. The same practice of paying people with beer was also found in ancient Egypt. The workers who built the pyramids each received a regular allotment of bread and two jugs containing roughly a gallon of beer in payment for their services. There was also a sliding scale of beer payments. Officials in charge of these state projects earned considerably more beer than the workers they supervised (Standage 2005, p. 37).

In both Mesopotamian and Egyptian societies, beer was also prescribed as a medicine for a variety of illnesses. The most ancient text detailing the medicinal uses of beer is a Sumerian text from Nippur dating from 2100 BCE that contains an extended list of beer-based concoctions. Egyptian pharmacology was no less explicit in prescribing beer. The Ebers Papyrus from 1550 BCE contains many beer-based recipes for treating a host of ailments. In fact, Egyptians considered beer and bread as being synonymous with health and well-being. These products were also believed to be necessary in the afterlife and were regularly put in the tombs of the departed (Standage 2005, p. 38). Sumerian society also recognized the importance

of beer in society and as necessary in the afterlife. The tomb of Queen Puabi in Ur, around 2500 BCE, contained her gold beer-drinking jug, bowl, and cup, as well as gold and silver straws with which to drink the beer (Gately 2008, p. 4).

Wine and Religion in Greece, Rome, and Medieval Europe

Perhaps the most important value ascribed to beer, wine, and fermented alcoholic drinks was a religious value. The fermentation process seemed magical to early people, and its effect on those who drank the beer or wine, the feeling of euphoria associated with intoxication, they took to be a spiritual experience. Since they believed that these drinks had a divine origin, they also believed that religious ceremonies should include offerings of these divine potions (Standage 2005, p. 19). Egyptian mythology credits the god Osiris with creating both beer and wine. He was also the god of the underworld, having been killed and then revived, and thus seemed a natural divine sponsor of the grape vine which dies back in the autumn and revives in the spring. Egyptians believed that worshipers celebrating Osiris by eating bread and wine were consuming the transubstantiated body and blood of their god. Throughout the Fertile Crescent the gods were prayed to and worshiped by offerings and libations of beer or wine (Gately 2008, p. 7).

The Greeks were exclusively wine drinkers. They believed that wine was a divine gift, and it played a central role in their religion and what they considered civilized life. They scorned beer as being a barbarian tippie that had no role in the decorum of civilized living. Their god of wine, Dionysus, a semi-immortal offspring of Zeus, came to Greece from the Middle East bringing with him the vine and knowledge of winemaking. Dionysus bears some resemblance to the Egyptian god of wine, Osiris, because of his association with the autumnal death and springtime rebirth of the grapevine (Gately 2008, p. 17). Like religions in the Fertile Crescent, Greek religion also encouraged the offerings of libations of wine to the gods both in formal ceremonies and in family

occasions for worship. A Greek city state or *polis* like Athens would sponsor public festivals where wine because of its religious association was offered to rich and poor alike (Gately 2008, p. 12). Because of the centrality of wine to their culture, the Greeks further developed the science of grape cultivation and the technology of vinification. In addition, Athens and other maritime Greek city states built up a very lucrative export trade in shipping amphorae of wine throughout the Mediterranean. Thus, wine also played an important role in Greek commercial life.

One of the main values associated with wine in Greek life was the role it played in the intellectual life of the polis. The Greeks, particularly the Athenians, initiated the tradition of the *symposium*, which was a private feast and wine-drinking party for educated men. Women were excluded from participating in these events, as they were excluded from other aspects of Athenian public life. After dinner had been served, a dinner in which no wine was consumed, a person was selected as the master of the ceremony, a symposiarch, who would decide what the guests would do when the drinking commenced (Gately 2008, pp. 21–2). Then the wine was prepared. The Greeks drank their wine after first mixing it with water and flavoring ingredients, such as pine resin, in a large bowl called a *krater*. Guests were then offered a cup of the wine from this large vessel. This tradition of being served from the same *krater* was similar to the Mesopotamian tradition of people each using a straw to drink beer out of the same jar. For both societies it was a custom that stressed the social and sharing nature of the experience.

One of the things that might go on at a symposium was that the symposiarch might ask the guests to sing or recite poetry. Or the participants might be called upon to speak about music or medicine (Varriano 2010, p. 37). In his philosophical dialogue, *Symposium*, Plato recounts a symposium in which the guests each made speeches about the nature of romantic love. Elsewhere in his dialogues (e.g., *Phaedo*), Plato, in the voice of his character Socrates, takes a disparaging view of the role of food and drink in educating one's mind and pursuing knowledge. Indulging the appetites

by drinking wine leads to sensuality and overcomes the rational faculty that leads to knowledge. In his dialogue, *Symposium*, Plato contrasts Socrates who leaves the drinking party sober with the other participants who end up befuddled by drink. In Book II of his dialogue, *Laws*, Plato is quite restrictive about who can consume wine.

However, Plato should not be taken as representative of Greek or Athenian views about the role of wine in cultural life. A countervailing tradition was that promoted by the Greek philosopher Epicurus. He believed that small gatherings of people at dinner parties where food and wine could be savored would encourage the social virtues of friendship and lead to the cultivation of intellectual interests. Rejecting Plato's advocacy of the immaterial nature of human consciousness, Epicurus was a materialist who believed that the appetites employed in moderation, especially for food and drink, fed the life of the mind. Epicurus established a school in Athens, and he and his followers held a banquet on the twentieth day of every month to feast, to drink wine, and to celebrate their friendship and the pleasures of life. In contrast to the symposium in which wine was consumed only after eating, the Epicurean banquet allowed food and wine to be consumed together. Because of these regular monthly banquets and their central role in the Epicurean philosophical perspective about the good life, Epicurus and his followers became known as the "Twentyers" (Symons 2007). The Epicurean emphasis on the role of the banquet in social life influenced the development of the *convivium* feast in Roman society. (I discuss the Roman *convivium* below.)

The Greeks colonized Sicily and the southern part of the Italian peninsula, and they brought with them their love of wine by extensively planting grapes. With its rich volcanic soil and mountainous terrain, Italy was ideally suited for grape cultivation; the Greeks referred to the Italian peninsula as "oenotria" or the land of wine. Greek arts and literature exerted a strong influence on Roman society as it expanded throughout the Mediterranean, and the Romans adopted the Greek passion for wine even in their desire for

military conquest. The Roman legionnaire was allotted a daily portion of wine. Not only was wine considered a healthy and uncontaminated drink, but it was believed to increase bodily strength and to assist in digesting food. It was also a very common anesthetic at a time when other remedies were unknown for treating the pain and strain of physical labor (Austin 1985, p. xvi).

From the days of the Roman republic, wine occupied a central place in the Roman household as opposed to beer which was considered the barbarian drink of northern Europe. In keeping with their love of Greek culture, the Romans adapted the Greek symposium and Epicurean banquet, transforming them into a festive dinner party that they called a *convivium*. Unlike the symposium, the convivium was not exclusively for men; women and men ate together. However, like the Epicurean banquet, the convivium encouraged consuming wine and food together. Yet, the convivium reflected the stratified nature of Roman society in that the wine was not served from a common mixing bowl or krater. Instead, each person mixed her or his own wine, and not all the participants quaffed the same wine. The highest status individuals at the dinner were served the best wine; those of lower social importance were served lesser-quality wines. Former slaves (freedmen) were served the worst wine in the cellar (Standage 2005, p. 78). In addition, the convivium was not primarily an occasion for intellectual entertainment. Since it allowed including lower-class people and those with little education, it provided an opportunity for doing business. Wine encouraged the brokering of deals.

When Emperor Constantine made Christianity the state religion of the Roman Empire in 313 CE, Roman society came face to face with the Church's ambivalent attitude towards drinking wine. Like Judaism, Christianity held that wine played a central role in the religion. In the Christian *New Testament*, Jesus is described as performing miracles with wine. At the Seder which was his Last Supper, he refers to the wine he is drinking as his blood. In keeping with that pronouncement, Christians were expected to consume wine as part of the ceremony of the

Eucharist. However, the secular consuming of wine posed a problem. As a religion focused on the afterlife and wary of the pursuits of the flesh, Christianity considered gluttony, which included the excessive drinking of wine, to be a deadly sin. In his *Pedagogia* written during the third century CE, St. Clement of Alexandria proposed that aside from the sacramental partaking of wine, women and young men should not drink wine but should stick to water. Only older men should be allowed to consume wine, and they should not try to cultivate an aesthetic interest in fine wine but be content with whatever was offered to them or was available (Gately 2008, pp. 44–47).

Although the Church had reservations about consuming alcoholic beverages, during the Middle Ages alcohol was still highly valued for religious, medicinal, and mercantile reasons throughout Europe. Christian monks in their monasteries cultivated vines wherever grapes would grow. Although they made wine for use in the celebration of the Mass, they also made wine to serve at meals in the monastery's refectory. Since many hospitals were started by monks, wine was also produced to be used as a medicine. In fact, many of the great vineyards of Europe were originally established by monks. By the thirteenth century, trade increased throughout northern Europe spurred in part by the Hanseatic League. Two of the league's most successful items of trade were the new hops-brewed beer and wine which began to be widely produced and consumed as a popular beverage (Austin 1985, p. 95). A huge export trade in wine developed shipping wine from Bordeaux and other ports in western France to England and the Netherlands. However, alcohol consumption began to change in Europe due to the discovery of distillation.

The Distillation of Alcohol and the "Water of Life"

Up until the late Middle Ages, the only alcoholic drinks known were fermented beverages such as mead, wine, and beer. That was soon to change once European entrepreneurs became aware of the experiments with *distillation* that were being

conducted by Muslim chemists. The word "alcohol" is of Arabic origin and is derived from the word "kohl" which referred to the dark eye cosmetic used by the ancient Egyptians. By experimenting with the process of making kohl, and by using a vessel with a long spout called an *alembic*, Muslim chemists discovered that one could produce an unusual liquid from heating wine (Gately 2008, p. 72). Since alcohol has a lower boiling point than water, by heating wine or any fermented liquid in an alembic, or vessel with a spout, or one connected to a copper coil, one could collect the alcohol vapors and condense them into a liquid with some surprising properties. Since Islam prohibited the drinking of wine or alcoholic beverages, Muslim chemists considered the distillation of wine to be only a curious scientific discovery.

The Italians, however, realized the significance of this discovery, and in the twelfth century CE, apothecaries in Salerno began writing about a new distilled liquid (*aqua ardens*, so-called because it could catch fire) and proposing it as a medicinal drink. By 1320 CE an enterprising merchant in Modena was distilling large quantities of alcohol for sale not only as a medicine but also as an invigorating beverage that was now referred to as *aqua vitae* or "water of life." It was realized that *aqua vitae* was the causally significant ingredient in wine or beer, and by itself in sufficient quantity, it could produce major changes in human behavior. Venice soon became a major port for distributing this potent beverage to the rest of Europe; however, before long the technology for producing alcohol had quickly spread throughout the continent (Forbes 1948, pp. 87–95).

Because it was more potent than wine or beer, distilled alcohol came to have its own value as the "water of life." The name, *aqua vitae*, was adapted into a number of European languages: the French called the distillation of fermented fruit beverages "eau de vie," and the Scandinavians distilled a spirit they called "akvavit." Even the word "whiskey" is derived from the Gaelic expression for "water of life." Alcohol was credited with being the water of life because it was believed to be a *spirit* (another name

commonly used for alcohol) or a substance that had a major animating effect on the body and could induce radical changes in consciousness.

In his book *The Passions of the Soul* (1649), René Descartes proposed that human emotions were not produced by someone actively willing them, but they were passively brought about by specific agents in the body. Descartes referred to these agents as “animal spirits.” With his mechanical view about the operations of the body, Descartes thought that these animal spirits hydraulically affected the brain which in turn, according to his interactionist theory of mental-corporeal causation, produced changes in human consciousness. His views about these “spirits” producing emotional changes in human beings were probably influenced by the widespread use at the time of distilled alcoholic drinks which could make imbibers become loud and boisterous, or mean and aggressive, or even morose. Because of this respect for alcohol as an agent that could affect the mind and the body, there existed a popular belief that alcohol was a potent elixir that could not only cure illness but revive people who had collapsed in shock. In the pharmacopeia of the time, it was valued accordingly. Even today there still lingers a holdover of this Renaissance belief in the medicinal power of distilled spirits. Although there is no contemporary medical evidence to support the view, some people still believe that if someone has collapsed due to a shocking experience, the remedy should be to get that individual to drink a glass of brandy.

Distilled beverages also had a profound effect on the late Renaissance emergence of European commerce and the future course of European colonial expansion. Spirits could be distilled not only from wine and beer but also from sugarcane or molasses (rum) and potatoes (vodka or schnapps), as well as from many other sources. One of the evil results was the African slave trade that originally depended on using spirits to buy enslaved African people to work in the sugarcane fields of the Caribbean islands. A lot of the sugar that was produced was converted into molasses which then was distilled into rum and sold in Europe or used to buy more slaves in Africa. However, by the eighteenth century, a positive

effect resulting from distillation was that farmers in the Americas and Europe that had previously had trouble getting their perishable produce to market could now take their grains or potatoes and make a spirit from them. For example, whiskey distilled from corn, rye, or barley was much easier to transport to market, and it would not perish. In fact, it would improve with age. Because there was a ready demand for spirits, they could even be used as a kind of currency (Gately 2008, p. 216). Spirits could also be added to wine, as they were to port and sherry, which made these fortified wines less susceptible to spoilage when transported by ship.

The Aesthetic Value of Alcohol and the Rise of Gastronomy

The eighteenth century saw a significant rise in the philosophical interest in what we now would refer to as aesthetic experience. Because the term “aesthetic” did not gain currency until the nineteenth century, the common philosophical term for the appreciative experience of art and nature was “taste.” Although many philosophers distinguished the critical taste for art and music from the gustatory experience of taste involved in alimentation, several philosophers recognized the metaphorical connection between the critical taste for art and the literal taste of gustation. These philosophers used the discriminating and appreciative tasting of fine wines as examples of how literal taste could lead to the development of critical taste. For example, in his essay “Of the Standard of Taste” (1757), David Hume used the example of a discriminative tasting of wines to explain his notion of “delicacy of imagination” which he thought was a requirement for an individual having sound critical taste. He thought that to be a good judge of the quality of wine, one had to be able to discern the minute constituents of the wine that added to or detracted from its being a good wine (Hume 1987). Voltaire, in “An Essay on Taste” (1757), also used the example of being able to discriminate the subtle qualities that give a wine its distinctive character as a sign of someone possessing good taste (Voltaire 1970).

Nevertheless, there were philosophers who opposed the view that wine could be an object of critical interest. In his influential work on aesthetics, *Critique of Judgment* (1790), Immanuel Kant argued that food and wine could not be objects of aesthetic interest. They were merely objects of personal preference and could not sustain the imaginative interest that works of art or objects of natural beauty could (Kant 1987). However, Hume's and Voltaire's use of such examples shows a developing respect for fine wines as objects of critical appreciation, a respect that was also reflected in the interests of the emerging middle classes in Europe and elsewhere.

At the end of the eighteenth century and beginning of the nineteenth century, several significant changes took place in European culture that contributed to this developing critical interest in fine wine. Whereas in earlier times lavish dining and the consuming of expensive wines had been restricted to the palaces of the aristocracy, after the French Revolution restaurants proliferated which provided innovative food and drink to anyone with the resources to pay for these meals. With the appearance of restaurants, there also emerged an aesthetic interest in fine dining that came to be referred to as "gastronomy."

One of the popularizers of this aesthetic valuing of sophisticated dining and drinking of good wines was Jean Anthelme Brillat-Savarin, who published a widely read volume, *The Physiology of Taste* (1825). Brillat-Savarin championed "the pleasures of the table" which included the contemplative appreciation of fine wine (Brillat-Savarin 1978). He championed a "transcendental gastronomy" that challenged Kant's view that wine could only be a personal pleasure, one immediately sensed and not affording any opportunity for imaginative and contemplative engagement. Brillat-Savarin proposed a more sophisticated account of how we sense gustatory objects like wine, and he stressed the extended temporal progression involved in swallowing what we consume. His account of the extended nature of tasting allowed for the imaginative aesthetic engagement with what we were consuming.

In accordance with his popular views on contemplative tasting, wine, beer, and other alcoholic beverages began to be recognized as beverages worthy of aesthetic attention.

With the spread of the railways in the nineteenth century, it now became much easier to obtain excellent wines from distant places. This easier availability of these wines and produce in the capitals of Europe further promoted the aesthetic interest in wines and other alcoholic beverages. This greater appreciative interest in wine, beer, and distilled spirits has continued to grow in the twenty-first century. There is now a global market for, as well as interest in, these products. Wonderful wines are now made in South Africa, New Zealand, Australia, and countries in North and South America. Distinctive beers are brewed all over the world, and Japanese whiskey is no less excellent than the best scotch and bourbon.

Although Kant resisted accepting wine or food as being potential objects of aesthetic interest, he did realize that small dinner parties at which wine or spirits were served were very valuable social occasions. These dinner parties brought people together in a relaxed and convivial setting that allowed them to exchange and share ideas (Kant 2006; Cohen 2008). Just as the Greek symposium and the Epicurean banquet attempted to promote a convivial exchange of ideas, so one can take Kant as urging the value of similar social meetings. He also recognized the positive role that alcoholic beverages could play in these social gatherings. In the twenty-first century, another philosopher, Roger Scruton, has called for the reviving of something like the symposium tradition in which people would get together for a meal and to savor wine. He believes this meeting of minds aided by the consuming of wines of interest would also promote and further intellectual exchange (Scruton 2009).

Summary

From their creation at the dawn of human communal life, alcoholic beverages have been recognized as valuable for a variety of reasons. Many

cultures valued them for religious reasons, finding in them a mystical and animating power and consequently using them in religious ceremonies. Fermented drinks like beer and wine served to promote social and economic development. As early forms of medicine, they were used to try to cure the sick and to ease the pain of those who labored. They were valued as aesthetic objects in antiquity, and today they attract an even broader aesthetic interest. Finally, their fostering of a convivial relationship among people, bringing people together to share ideas, continues to be recognized as an important and valuable social catalyst in contemporary life.

Synonyms

Artiste provocateur; Food terrorism; Neophobia, visual culture; Pica; Taboo

Introduction

Alimentary delinquency, a term originally coined by French sociologist Pierre Aimez, will be used here to designate a wide range of eating practices that are generally considered by society at large as aberrant and as going beyond the normal, comprising a number of disturbed ingestion practices that are widely considered as taboo and/or excessive: ingestion of nonfood (nonnutritive) items or of excessive amounts of food, doing things with food that should not be done, and forcing/duping people into eating something they would not normally eat. Although evidence of alimentary delinquency as described dates back to antiquity, it will be discussed here as specific to the modern, contemporary period, as a symptom of “gastro-anomy,” a term coined by Claude Fischler to describe the consequences on eating and food-making practices of the bio-cultural

crisis experienced by modern eaters. Fischler and other sociologists and historians of food maintain that eating practices in modern societies have undergone a complex transformation in the shift from agrarian to post-agrarian societies, which in turn has engendered confusion and conflict surrounding eating practices. Alimentary delinquency is thus a manifestation of this bio-cultural crisis and will be outlined here in four categories: alimentary delinquency as the province of eating practices from other cultures, notably as a prominent discourse in travel literature; involuntary alimentary delinquency, recognized by mental healthcare professionals as pica, where subjects respond to oral cravings and drives beyond their ability to control; wilful acts of alimentary delinquency especially as they are presented in visual, graphic, and plastic art forms that are designed to provoke, disturb, and shock; and alimentary delinquency in the stricter legalistic sense, in cases of negligent or wilful food contamination and adulteration.

Alimentary delinquency as such lies at the crossroads of what can be eaten and what should be eaten and is central to making sense of our physical existence. More than the actual incidence of aberrant eating practices which in themselves are relatively rare, it will be maintained that the impact and significance of alimentary delinquency lies mainly in the collective imaginary: in the many conflicts that it exposes within conceptual issues related to the health and nutritional discourse around traditional food and eating practices; as well as in the “omnivore’s paradox” that pulls modern eaters between neophobia and neophilia.

Cannibalism as well as other forms of disturbed eating, such as eating disorders, are indeed forms of alimentary delinquency and are dealt with in separate entries.

Alimentary Delinquency and the Food of Others

Travel literature through the ages, as well as more recent cookery and travel programs on television and the internet, places a particular critical emphasis on the eating customs of other societies.

Although such accounts may very readily celebrate the diversity of culinary traditions around the world, they may just as readily be part of another tradition of being condescending to and denigrating other cultures for the food they eat and how they consume it, indicating that they may not have attained the levels of sophistication and civilization necessary for proper dining. Just as cannibalism has been used by various human groups to denounce others as fearful barbarians, eating habits of certain societies are described as alimentary delinquency to bolster descriptions of these societies as barbaric and uncivilized or as simply peculiar. Although it is impossible to stand outside of one’s culture and speak about appropriate and inappropriate foods, this has never stopped chroniclers visiting other cultures from expressing a full range of reactions to the alimentary delinquency perceived in other cuisines, ranging from curiosity, amusement, and incredulity to shock, disgust, and outright moral outrage.

Although amusement coupled with mild ridicule may accompany stereotypical accounts of the French and frog legs and snails, the Congolese and termites, or the Scottish eating haggis, this amusement can quickly turn to more severe condemnation when questions of cruelty or morality arise in equally stereotypical accounts of Koreans eating dog, Chinese eating live monkeys, or even Europeans eating horsemeat. The foods that are commonly put under the spotlight in such chronicles fall under two categories: those for which the gustatory experience itself is noteworthy – for example, *surströmming*, fermented Baltic herring in Sweden that results in a primeval stew, or even very pungent cheeses from areas of central Europe. A second category would comprise zoophagic foods in which little effort has been made to camouflage the animal nature of the foods presented. The inherent cruelty of the cultures visited is often cited in many travelogues especially in places where live food – from fish to primates – is consumed. Such foods that mimic life and meals that present the spectacle of life and death remind the visitor of the original state of food and also of the eater’s very mortality. Needless to say, the shock of witnessing and participating in such meals is much more potent than any

consideration of taste. Consider the overwhelmed reaction of Richard Gordon Smith in his 1907 account of being presented a live yet carved fish to eat in Japan by a proud local chef. These accounts focus relentlessly on meals that force the diner to confront and to contemplate the sacrifice made and the fact that life continues through the death of other beings – a fact that modern societies go to great lengths to obscure and dissimulate through preparations that conceal the animal nature of meat and the virtual elimination of offal and any parts of the animal that could suggest the animality and corporeality of both cook and eater. A further form of outrage may indeed be of a moral nature and focus on the ingestion of foods considered as taboo or forbidden especially, but not exclusively, on religious grounds, where the simple mention of a society's diet can be used to condemn entire cultures as sinful and immoral. Numerous accounts have been written, as detailed, for example, by Eric Dursteler, describing the moral indignation of travelers from Muslim or Judaic cultures that describe a cuisine of "infidels," whose table manners are questionable and who sustain themselves on abominable forbidden foods. The Internet teems with reports, testimonies, and, of course, photographs of all that modern travelers, especially the vicarious ones, may find bizarre, cruel, and stomach-turning from all corners of the earth.

Involuntary Alimentary Delinquency: Pica

Pica, from the Latin word for the omnivorous magpie, is classified in the *Diagnostic and Statistical Manual IV* of the American Psychiatric Association as a psychological disorder in which the subject repeatedly and obsessively craves and ingests nonnutritive substances. Subtypes of pica are virtually innumerable and are characterized by the substance consumed, ranging from dirt to clay, plastic, glass, feces, hair, etc. It has been difficult to assess the prevalence of pica, but studies show that it occurs more commonly in women and children, and very often in conjunction with another psychological disorder; for example, it is

common in autistic subjects. It is only considered as inappropriate behavior when it occurs beyond the developmental level of the individual. Therefore an infant mouthing a stone will not raise as much concern as a woman who incessantly eats sand or sofa cushions. Given that pica occurs mainly in women and children one common explanation for the phenomenon is that it is the result of nutritional deficiency. Although the ingestion of plastic and other synthetic materials is not uncommon in pica, organic substances such as clay, dirt, hair, nails, etc. are far more prevalent, suggesting that pica might not only be a sign of developmental disability but that it might indeed be indicative of an attempt by the subject to compensate for lacking nutrients. The ingestion of nonnutritive substances is only considered as a disorder when it occurs outside of culturally sanctioned practices. Many of these culturally sanctioned practices occur among women and especially pregnant women who practice various forms of geophagia, i.e., earth eating, in places all over the globe. Local studies have been carried out among women, and especially pregnant women, who ingest clay, stones, and soil in places as far from each other as Kenya, where women practice odowa, the ingestion of soft stones, to Saudi Arabia, where studies found pregnant women who consumed ice, plaster, and paper, to the state of Georgia in the United States, where pregnant women have long ingested kaolin, or white clay. Such studies explain that pica in these cases is an attempt to ingest vitamins and minerals lacking due to the surplus nutritional demands of pregnancy and, perhaps, the added stress of pregnancy. Women who practice geophagia when pregnant are shown to have lower hemoglobin levels and pica is often explained as a means to compensate for this deficiency. Such cases of pica can obviously be associated with the commonly evoked dietary "cravings" of pregnant women, which can at times be classified as alimentary delinquency.

Non-culturally sanctioned pica more clearly enters the realm of alimentary delinquency. Incidences of pica comprise the full range of all that could be possibly ingested and are explained by psychologists as being related to developmental

difficulties. The variety of items consumed in such cases seems only to be limited by one's capacity to ingest them and, even so, many of the items consumed are simply impossible to digest. Subjects suffering from pica are obviously doing great harm to their bodies. Pica, much like bulimia, invariably takes place in private away from the shame and condemnation of others. Treatment for pica focuses on behavior modification, from aversion therapy to positive reinforcement therapy, exposure therapy, and discrimination training.

Although the incidence of pica is relatively rare and could be aligned with other "shameful" eating disorders which mainly affect women such as bulimia and anorexia nervosa, the very notion of ingesting nonfood substances is intriguing to the general public and has been a typical feature of circus sideshow acts. The spectacular side of pica becomes more apparent when considering the 2012 reality TV series entitled *My Strange Addiction* on The Learning Channel, which makes a public spectacle of pica by featuring entire episodes devoted to one person's particular and peculiar variety of pica – from the more classical varieties in which organic matters such as clay, dirt, sand, or hair is ingested to far more disturbing cases in which subjects ingest plastic, tires, sofa cushions, cat food, and mothballs, for example. The subjects are almost exclusively female and each episode typically includes segments in which the featured eater demonstrates how and in what circumstances they eat their preferred "food" – usually in small bites and always in secret. They are also given the opportunity to explain the gratification they derive from satisfying their cravings. Texture is often evoked in terms of either softness or crunchiness. Each episode also features a moment of confession where the subject reveals her craving to an incredulous friend or family member or a medical professional. Emphasis is placed on the pleasure derived from pica and the program rarely presents the subjects as suffering psychologically from their cravings. As such the program itself serves as a form of exposure therapy in that the subjects are confronting their craving in a very public fashion and they are being clearly informed of the health risks that they face.

Willful Alimentary Delinquency: Defying Taboo and the *Artiste Provocateur*

As much as the very real cases of pica require the attention of medical professionals and mental health practitioners, alimentary delinquency, because it is positioned at the crossroads of what can be eaten and what should be eaten, captures the imaginaries of observers and spectators and thrives in very visible forms, as demonstrated by the visual attention given to pica in *My Strange Addiction*.

Artworks and other social acts based on food and eating practices can be divided into two broad schools: the well-behaved and the badly behaved. Well-behaved food art is concerned with harmony in the process of creation of food, the mise-en-scène of dishes themselves, and the staging of elaborate meals, often with real eating subjects. The work of Japanese food artist Ayako Suwa is of note in this domain, with the success of her touring pop-up "guerilla" restaurants/exhibits in international capitals, which place diners in unique stylized settings where they are presented with a series of bite-sized delicacies fashioned as *objets d'art*. We can also look at the harmonious tradition in the use of food displayed in such films as *Babette's Feast* (Gabriel Axel, Denmark 1987), *Julie and Julia* (Nora Ephron, USA 2009), *Eat, Drink, Man, Woman* (Ang Lee, China 1994), or *Like Water for Chocolate* (Alfonso Arau, Mexico 1992) to name but a few, where good food that is aesthetically presented is linked to tradition, heritage, and the positive moral bearings of those who prepare and eat the food. These notions can also be extended to many cookbooks and televised cookery programs that aim to teach people to be mindful cooks and appreciative eaters of good, well-presented food, emphasizing the visual more than any other sensorial organ involved in eating.

While "well-behaved" art places a premium on "gastro-porn" and the elegant mise-en-scène of food in enticing contexts, it is certainly in the "badly behaved" area where alimentary delinquency is prevalent as a form of artistic expression and manifests itself in quite different ways. More concerned with the process of ingestion itself and

the bodily experience of eating, alimentary delinquency emphasizes corporeality and the link between the ingestion of food and other acts performed with/upon the body's orifices. Foods featured in acts of alimentary delinquency are also intended to shock and disgust and are more often than not raw, viscous, and zoophagic in nature.

The early nineteenth-century European avant-garde Futurists and Surrealists began embracing the disturbing potential of food in numerous works and public pranks, notably Filippo Marinetti's *The Futurist Cookbook*. The *Eat Art* works of German artist Daniel Spoerri that appeared throughout the 1960s continued and expanded this trend, displaying unfinished dinners and messy kitchen counter and table tops as framed works of art, staging acts of auto-cannibalism, and projecting playful, yet negative, anti-aesthetic resonances around food and eating. Judy Chicago's widely acclaimed touring exhibit entitled *The Dinner Party* (1974–1979) featured multicolored dishes painted with highly stylized depictions of food-like vulvas which were openly displayed in homage to prominent women in history, pointing at the same time to the complexity of woman's problematic roles as both cooks and eaters.

While Spoerri toyed with cannibalism, the ultimate culinary act of savagery, other performance artists have gone further, willingly submitting their bodies for the purposes of creating such spectacles. In 2003, the Enema Collective in Havana made blood sausages according to a traditional Cuban recipe using blood drawn from the collective's members and displayed the sausages as artworks at exhibits and other events. Although these sausages were made to be contemplated and not consumed, art did meet reality in a similar yet unrelated incident, when in 2006 two members of the German Air Force were discovered in a human blood sausage making operation in which they collected the blood of fellow officers and prepared the sausages also according to a traditional recipe of one of their grandmothers.

More recently, Japanese asexual Mao Sugiyama had his penis and testicles surgically removed and offered to cook and serve them to five bidders at an event organized in Tokyo in

2012. The event was also attended with much fanfare by 70 other guests/spectators who were served beef or crocodile dinners and, of course, availed the opportunity to watch the five lucky guests dine on Sugiyama's genital delicacy, prepared with the advice of leading Tokyo chefs. The event was entirely staged with the same level of decorum and *mise-en-scène* as a performance meal by the aforementioned "well-behaved" Ayako Suwa. Eventually, obscenity charges were brought against Sugiyama for exhibiting pictures of his severed penis and not for the staged act of cannibalism, designed, according to the artist, to raise awareness about the existence and turmoil of asexuals.

Filmmakers have also been among the principal exploiters of alimentary delinquency, and the list of well-behaved films mentioned above can be complemented by an even longer list of badly behaved films which, like other works of art that feature alimentary delinquency, are generally considered as aggressive and can be seen as mounting direct attacks against the conventional comforts and pleasures associated not only with consuming food but also with consuming art. In this light, one can consider the actor Divine's "spatiotemporal" ingurgitation of dog excrement in the epilogue of John Waters' 1972 *Pink Flamingos*. Similar types of shocking and bizarre scenes and themes around food and eating are featured, for example, in Marco Ferreri's *La Grande Bouffe*, Luis Buñuel's *Phantom of Liberty*, Dusan Makavejev's *Sweet Movie*, Pier Paolo Pasolini's *Salò o le 120 Giornate di Sodoma*, or Peter Greenaway's *The Cook, the Thief, His Wife and Her Lover*, to name but a few. To this list of "art" films can also be added a considerable number of American and Italian horror films of the 1970s and 1980s that feature repeated acts of cannibalism. As such, alimentary delinquency has flourished in filmic forms of the lowest and highest statures in terms of cultural esteem.

The spectacle that alimentary delinquency offers is graphic and frontal and what matters most is display, directed at the spectator. Such exhibits and acts elicit disgust and shock from observers and spectators, and, like pica, dissect the act of eating from any nourishing function.

Their primary effect or purpose is not to provide entertainment or aesthetic pleasure, but to disturb and to jolt, striking out at the passivity of the viewer. Such works are often praised and condemned for the very same reasons; they are grotesque, destructive, chaotic, and repulsive.

Alimentary Delinquency as Crime

Another type of alimentary delinquency that must finally be considered occurs in a stricter ethical and legal sense in the form of scandals and scares that arise from mass food contaminations and the incorrect labeling of foods purchased in supermarkets or restaurants. Food scares are centered around a wide range of potential hazards all along the food supply chain that can result in a host of food-borne illnesses of varying degrees of seriousness. It is widely believed that many incidents of contamination – in baby milk formulas, salmonella or *E. coli* outbreaks, for example – are attributable to negligent industrialized food processing methods, and questions are often posed by investigative journalists regarding the responsibility of the dominant food corporations. Attention drawn, for example, to the potential legal culpability of food producers who, perhaps knowingly, alter the contents of their products or insert “addictive” levels of sugars and trans fats in their products. While many indignant members of the public suspect industrial food giants of wanton negligence, establishing proof of intent and initiating change in certain production processes have been difficult. Officials or groups attempting to intervene by outlawing certain practices in the name of public health and/or consumer protection, using many of the same arguments that were used successfully against tobacco companies, face daunting legal challenges. The attempt made by New York Mayor Michael Bloomberg in 2013 to ban the sale of sugar-laden soft drinks in “super-sized” recipients in an effort to ward off upwardly trending obesity and its subsequent burden on healthcare systems was struck down by the courts in the name of civil liberties. Such incidents are coupled with other 2013 scandals involving the undisclosed yet widespread substitution of cheap

horsemeat for beef in frozen meals sold in North America and Europe and the use of pork sold as reindeer meat in Scandinavia. Although there was no health risk involved in these inscrutable and deceptive practices, they have prompted consumer watchdog groups to increase demands on government agencies for greater vigilance and accountability in all steps of the industrial food chain.

Although actual cases of criminal mass food adulteration have been rare – the most prominent case occurring in Oregon in 1984 where 751 people became ill after a religious cult infected area salad bars with salmonella – the potential of “food terrorism” is considered as a real and current threat by national and world health organizations. However, the greatest threat posed by food terrorism is not so much the widespread physical harm that could be caused to the population, as much as the potential economic damage incurred, as reactions to contaminated foods are immediate and result in speedy recalls that in turn have a long-term financial impact on food producers and retailers. Fortunately, actual incidents of food contamination, much like the disturbed eating practices described above, are relatively rare, yet they have a long shelf life in the imaginaries of eaters and have prompted modern eaters to become more mindful and responsible in their eating practices and to ask essential questions about the ways in which food is produced and consumed.

An important aspect of food scandals regarding alimentary delinquency is the manner in which they are exposed to the public by industry whistle-blowers and investigative journalists. Such revelations often elicit heightened indignation and reaction especially when accompanied by imagery or graphic description. One of the first food scandals to receive nationwide condemnation in the United States was the result of realistic and visually evocative descriptions of meat-packing practices in Chicago in Upton Sinclair's 1903 *The Jungle*. Sinclair's detailed descriptions are among the factors that contributed to the eventual creation of the US Food and Drug Administration. Meat has remained central to many food scandals. In 2012 it was revealed that many North American industrial ground beef preparations,

notably hamburgers, contain alarming quantities of a viscous slaughterhouse by-product derived from centrifuging leftover offal, bones, cuttings, and blood that is used as a filler. Known in the industry by the euphemism “lean finely textured beef,” its prevalent use was revealed to the public in the press with the evocative term “pink slime.” More than any other technique, the animal rights group People for the Ethical Treatment of Animals (PETA) depends on photographs and videos taken from behind the closed doors of animal confinement pens and slaughterhouses to arouse the shock and indignation of consumers and to garner support for their work against animal cruelty. Under pressure from the meat lobby, states have taken measures in 2013 to denounce and ban the use of such imagery by whistle-blowers, claiming that the images are unlawfully obtained and are frequently used to distort the truth while at the same time acknowledging that raw footage and terms like “pink slime” go a long way in raising consumer awareness and demands.

Summary

Alimentary delinquency, as featured in travel literature, in cases of pica, in works of contemporary art, or in food scandals that are exposed in a heightened visual manner, is viscerally disturbing and elicits revulsion in both physical and moral forms. Creating spectacle and menace around the act of eating, it forces post-agrarian spectators-as-eaters to question “normal” eating practices, often through the use of shock and disgust, and points to the body as a potential site of suffering and disorder through the seemingly simple, and often unquestioned, act of eating. Michael Pollan, in his critique of the widespread mechanized mass production of food, but mainly of meat and the industrial slaughterhouse, is an advocate of the right to look, suggesting that slaughterhouses should remove their doors and take down their walls, exposing all of their methods to the eyes of the public, as hard it sometimes may be. According to Pollan, the very fact of being able to look inside the slaughterhouse would provoke profound changes in the ways that animals

are slaughtered and the ways that food itself is consumed. With its emphasis on the display and presentation of blatant images, alimentary delinquency challenges the modern eater, who prefers less and less to be confronted with the reality of his or her food and who, in a state of post-agrarian bio-cultural crisis, must confront the symbolic possibilities of food contamination, coprophagy, gorging, cannibalism, and the spectacle of human flesh turned to meat. Alimentary delinquency involves acts of representation, which, more than any real danger to eaters, disassociate the act of eating from actual nourishment and pave the way toward Pollan’s goal by eliciting eaters to think long and hard about food choices and the ways in which food is consumed.

AFNs; Agro-food networks; Alternative food geographies; Alternative or shortened food chains; Community food; Food justice initiatives; Local food movement; Short food supply chains

Introduction

The term “Alternative Food Networks” (AFNs) describes the practice and an academic body of work surrounding the emergence of alternative food practices that emerged in the 1990s as a reaction against the standardization, globalization, and unethical nature of the industrial food system. Common examples include community supported agriculture, farmers’ markets, fair trade, urban agriculture, specialized forms of organic agriculture, direct farm retail, and the slow food movement. AFNs seek to diversify and transform modern food provisioning by connecting ethical producers and consumers in more local, direct ways. They build on an ethics of environmental sustainability, social justice, and animal welfare. AFNs endorse the creation of new exchange models that support a return to community food production and demonstrate a commitment to social, economic, and environmental justice along the food chain. Produce from AFNs is often considered to be fresh, diverse, organic, quality, and “slow,” while networks are perceived as small-scale, short, traditional, community, local, and embedded. Goodman et al. (2011) chart two significant historical trajectories of AFNs that emerged from Western Europe and North America, resulting in different foci, objectives, and understandings. These trajectories are joined by AFNs from around the world. This entry discusses AFN

trajectories and their common characteristics of quality, embeddedness, locality, and directness. Various criticisms have been raised in AFN literature about the conflation of AFN types and characteristics, their predominance towards exclusivity, racism and elitism, and the impact of the capitalist market on their goals toward their desire to create an alternative food system.

AFNs from Europe

AFNs emerged in Europe from a combination of environmental and organic agriculture movements and as a consequence of agricultural reform due to the European Union Common Agricultural Policy (CAP). CAP reoriented rural development from a centralized, productivist policy toward a more decentralized approach that allowed for more multifunctional agriculture. Health and food safety concerns included an outbreak of Bovine spongiform encephalopathy in 2001. Such food scares prompted consumers to demand improved food quality control assurances desiring increased knowledge of how their food was produced and what it contained. European AFNs often arose from a rural base, linking the quality of a product to its region. This valuing of local, rural production was said to endorse “a Eurocentric rural imaginary and defend(s) its cultural identity against a US-dominated, corporate globalisation” (Goodman et al. 2011, p. 12). Such food movements may be indicative of “patrimonialization”: a French term used to describe how qualities of authenticity and heritage combine with food to produce a heightened sense of place toward the protection of rural landscapes. As such, European AFNs often arose from the motivation to protect rural agriculture from the consequences of global trade and standardization through revaluing local agriculture in the creation of new enterprises (Goodman et al. 2011). This shift towards a local, value-added produce is reflected by the Slow Food Movement that emerged in 1986 as protest against the arrival of the McDonalds’ restaurant chain in Rome.

AFNs from North America

AFNs in North America typically represent more radical, emancipatory, civic-led models. In the United States, AFNs grew from an array of counter culture movements that include the civil rights campaign, antiwar activism, and the environment movements of the late 1960s and 1970s. With its social and ecological critique of industrial agriculture and agribusiness, the back-to-the-land movement became a key influence. Publications such as the *Whole Earth Catalog* and *Mother Earth News* further inspired the desire to make a living from the land. Rural farmers became connected with urban consumers through local markets that further evolved into urban food cooperatives, buying groups, natural food stores, and communal restaurants. The organic food movement also emerged during this period. However its counter cultural origins were “conventionalized” (Guthman 2004) by scientific and industry bodies in the 1990s, transforming the practice into an institutionalized, multibillion dollar industry to become governed by federal legislation and regulations. The conversion of the organic food movement into a scientifically framed, commercialized form of sustainable agriculture have led some to relabel it “organic lite” (Guthman 2004) and to recognize it as part of the “corporate-organic foodscape” (Johnston et al. 2009). The emergence of the local food movement (LFM) challenged the conventionalization of the organic food sector to go “beyond organic,” instead placing emphasis on the creation of sustainable *community* food systems that employ environmentally friendly methods of urban and rural food production. Examples of the LFM in the United States include the 100 Mile Diet, the locavore movement, the establishment of local food policy councils, and the concepts of food miles and the ecological footprint.

A Global Emergence of AFNs

Until recently, the study and practice of AFNs had been mainly restricted to affluent countries such as Western Europe and North America. However

in recent years, the practice and study of AFNs has gained attention around the world including Eastern Europe, Asia and Africa. For example, in Poland consumer cooperatives are growing in popularity (Bilewicz and Śpiewak 2015) while in China there are examples of community supported agriculture, farmers' markets, buying clubs, and garden plot rentals (Si et al. 2015). Notably, AFNs should be acknowledged within the specific of the country and culture. Scholar such as Abrahams who discusses AFNs in Africa (2007, p. 20) recognize how the inclusion of the Global South in AFN literature opens up new lines of enquiry both within the Global South and between AFNs in the Global North and South. African AFNs parallel those in the North by exhibiting characteristics of SFSCs, quality, slow, local and cultural foods, and produce from direct farm sale. However, they differ with their focus not on the celebration of (alternative) consumption, a lifestyle statement, or a "romanticized return to the local" (Abrahams 2007, p. 20) but instead on issues of survival, cultural diversity, food poverty, and insecurity. Southern AFNs broaden the remit of northern AFNs to include grassroots led urban and periurban agriculture, local and cultural food provisioning networks that cater for the urban poor, and cultural and religious modes of provisioning (Abrahams 2007; Crush and Frayne 2011). These Southern African food pathways include informal markets, street traders, food vendors, and nonmarket approaches, such as receiving food from neighbors, the sharing of meals, eating food provided by others, and the borrowing of food. Importantly, southern AFNs do not represent simply a remnant informal economy. Instead, they occupy an alternative space as a reaction against increasingly dominant and inadequate supermarket provisioning, and to obtain previously unavailable cultural foods. Southern AFNs importantly contribute to our appreciation of AFNs by broadening the focus from a "hankering for the rural idyllic, nor the often elitist quest for conscience-quenching food" (Abrahams 2007, p. 28) to consider issues of survival, poverty, and cultural diversity. These issues are increasingly relevant for residents in the developing and developed worlds alike.

Characteristics of AFNs

While AFNs represent a broad umbrella group of alternative agricultural relationships and practices, their shared features include a focus on providing quality products, the establishment of trust between consumers and producers, and the sourcing of local produce often using direct exchange.

The "quality turn" refers to how consumers are turning away from distant processes in the global industrial food system to support local food systems where the quality of a product can be determined through knowing the local culinary culture and people in a region. Quality and trust is based in the transparency between the relationships of local producers and consumers. As such, "local" food in AFNs implies produce that is fresh, ethical, and environmentally friendly, as it conveys knowledge of what the produce contains and how it was grown. "Quality" food then represents relationships of trust and knowledge between grower and cook that are often, but not always, based on place (Goodman et al. 2011).

Recognizing that quality is socially constructed and contextual, scholars apply a variety of approaches to explore the distinction of "quality" in AFNs. Renting and colleagues (2003) categorize AFNs as "Short Food Supply Chains" (SFSCs) that can be created through relations of "product-in-place" or "process-in-place," where the former stresses the link between the product's location of production or producer, including environmental conditions and cultural traditions, while the latter highlights the bioprocesses associated with that place, such as health and environmentally -friendly methods of organic or GMO free production. Alternatively, Sonnino and Marsden (2006, p. 64) consider scalar aspects of the concept of "embeddedness," where "vertical embeddedness" represents impacts from wider institutional and governance system on the practice, while "horizontal embeddedness" signifies the local conditions and agency of where the product was grown. AFNs thus refocus food production from a faceless, global "external, elusive 'free' market" to "an active [tangible] construction of networks" that

embed quality in produce based on place (Renting et al. 2003, p. 399).

The concept of the “local” in AFN literature is also a relative and broadly applied term that varies according to size and scale. As recognized by Goodman and colleagues (Goodman et al. 2011, p. 11), “local” has become both “fluid in meaning,” “all embracing in scope,” and is used in numerous contexts, such as in sustainability movements that call for decentralization, , and self-sufficiency, and in community development programs that advocate for community control and equitable access to resources.

The application of various interpretations of the “local” in AFN literature includes use in SFSCs, territoriality and terroir, food miles, foodsheds, locality, bioregionalism, and local food networks (see Feagan 2007). These terms in turn embody different geographical, spatial, symbolic, material, social, technological, moral, and commercial meanings. For example, the phrases SFSCs and “terroir” describe European AFNs where local production refers to a return to an “authentic” traditional landscape. For SFSCs, AFNs denote the creation of niche, regional markets that add value to the product through specific quality definitions and conventions, such as labeling and certification, that highlight difference and thus desirability of the product (see Renting et al. 2003; Ilbery and Kneafsey 2000). The French terms, “territoriality” and “terroir,” connect the quality of products to place, espousing their ecological and cultural relationships to that territorial location. The use of food product origins through designated quality labels can then physically extend this symbolic connection to place, resulting in situations where the distance traveled by SFSCs may in fact be quite extensive. This use of food product labeling parallels a difference in interpretation between the terms, “local” and “locality,” as while “locality” foods may be consumed in place, they also have the ability to travel by mobilizing cultural signifiers to be consumed elsewhere by distant consumers in the marketplace. Examples of SFSCs and terroir include direct sales of niche, specialty markets, community supported agriculture and farmers’ markets while emerging online

technologies may offer glimpses into the relationships between growers and consumers. According to Goodman et al. (2011, pp. 79–81), the social equity and environmental justice assumptions of AFNs may be challenged when phrases such as “local food networks” instead reposition producers as profit seekers in their translation of quality from the local to be expressed in extra-regional, commercial, and industrial worlds, supporting new forms of direct marketing.

Alternatively, “foodsheds” in AFN literature represents a naturally and spatially defined area that includes both the biological resources and the people who work in the region to produce food (Renting et al. 2003). This form of “local” implies that AFNs would need to be located in regions with adequate resources to grow sufficient food. Furthermore, the term, “bioregionalism” is used to embed and revalue regional produce in competition with products from the conventional market (Sonnino and Marsden 2006, p. 77). While for some AFN scholars, the “local turn” may be interpreted as a form of “defensive localism,” a term first coined by Winter (2003) that refers to a politics of protectionism that may promote political urban boundaries to the detriment of others, threatening the principles of AFNs.

Criticisms Within AFN Literature

AFN literature has been criticized in three broad camps: issues of conflation of AFN characteristics and between different types of AFNs; issues of exclusivity, racism, and elitism; and the corrosive influence of the capitalist market on activist goals.

The Conflation of Different Types and Characteristics of AFNs

Due to its broad coverage of activities with various modes of exchange, motivations, and participation, AFN literature represents more what AFNs are *not*, rather than what they are. AFNs represent a loose mix of actors, activities, philosophies, and diets that form an eclectic group in opposition to the dominant, global, industrial food system and what it represents. “Local” pits itself against “global,” “slow” food against “fast,” and

“quality” against “junk,” while placing a face on products that are otherwise faceless and placeless to add value by way of region and production for an other-than-purely-economic purpose. As such, AFN literature tends to inconsistently apply concepts and overgeneralize terms that effectively ignore specific historical, social, biological, and political contexts. Such conflation confuses understandings, weakens arguments in favor of alternatives, and undermines actions to further develop the efficacy of AFNs. Furthermore, the dualistic and reductionist practice of placing AFNs into either “mainstream conventional” or “alternative” systems can be misleading as in reality, “food systems rarely operate exclusively within these artificially circumscribed boundaries, they dip into, or borrow from, diverse logics over time” (Tregear 2011, p. 424). The concept of the “local trap” coined by Born and Purcell (2006) acknowledges the issues that can occur when the local is assumed to be desirable. For example, local strategies may not actually produce beneficial outcomes and the local must rather be understood with regards to the specific contexts of that particular food system. Rather than scale as the focal point, other factors such as the biological resources, desires and needs of participants, and the agenda of those who are able to make the decisions must instead be examined.

Issues of Exclusivity, Racism, and Elitism

The boundaries that separate “alternative” from “conventional” food systems also act as exclusionary boundaries from equitable participation. AFNs have been criticized for privileging white, middle-class “do-gooders” to instigate, access, and control alternative means of production. North American scholars speak of the “whiteness” of AFN spaces where access to AFN activities may be limited on racial grounds as people involved may “have the wealth to buy organic, the inherited or schooled knowledge about nutrition or the environment and they are politically liberal to left” (Slocum 2007, p. 522). Alkon and McCullen (2011) document that it is mainly “whites” who comprise the majority of California’s organic farmers and who also tend

to dominate attendance at farmers’ markets and community supported agriculture programs. However, more than simply outnumbering people from different racial backgrounds, AFN spaces are “coded white” (Guthman 2008) where the “white imaginary of farmers” reflects an “affluent, liberal habitus of whiteness” (Alkon and McCullen 2011, p. 939). This imaginary is based on the struggles of small-scale, white farmers while masking the contributions and struggles of people of color in food production.

What Is Alternative and the Influence of the Capitalist Market on Activist Goals

Overall, AFN literature speaks of alternative agrofood practices that seek to provide innovative templates for social change against the global industrial food system. However, how these models are exactly *alternative* often remains unclear. Are authors referring to “alternative” relationships between producers and consumers, in their values, in what they offer, or in how they distribute surplus profit? For which people in AFN initiatives do they represent alterity? Do all AFNs – in their very broad range of characteristics – unite to stand in opposition to the industrial food system?

One aspect that remains unclear is the relationship between AFNs and the capitalist market. Many AFNs strive to continue to provide alternative relations of production whilst remaining within the capitalist market, such as quality or “green” niche market models. These examples have been criticized for reinforcing unequal power relationships and dynamics inherent within capitalist market relations, rather than changing them. This reinforcement of the status quo by the capitalist market may be achieved in various ways, such as through commodification, individualization, scale, and conflation. The process of commodification prioritizes economic values over use, and social and environmental justice values, resulting in one commodity being pitched against another in order to compete in the marketplace. As an example, market-based AFNs that valorize place and quality may in fact pit characteristics of local against local, and quality against quality, in order to survive.

This leads to the question if market-led, economic-biased value AFN models can address such systemic and structural politics? Within a specialist market niche, this competitive quality turn can exclude those it was actually originally established to help, for example, the poorest producers of Fair Trade who are unable to meet the international quality standards required for their participation. The “shortness” or “localness” of an AFN also presumes that greater knowledge is exchanged between producer and consumer. However, this acquired knowledge also redistributes responsibility to the consumer, placing them under the burden to “buy” their way to a fairer food system. Rather than deliver greater knowledge and insight about how the food system operates, the individualization of responsibility via customers dietary choices instead *masks* the real issues at hand, diverting attention from embedded political, economic, and infrastructure issues within the capitalist, industrial food system (Harris 2009). Furthermore, as an AFN becomes integrated – or mainstreamed – within the capitalist marketplace with their sales extending beyond the local to a global level, they face further obstruction in revealing their specificity of place and politics.

Economic geographer, Amin argues that such distanced food networks require a reintroduction of politics, specifying a need for a “shift in emphasis from the politics of place to a politics in place,” from place-based knowledge to a “nonterritorial way of viewing place politics” (Amin 2002, p. 397). In a study of her students who strive “to bring good food to others” in their fieldwork volunteering at food insecurity organizations, Guthman (2008) describes how – rather than improving people’s diets – the students’ actions instead divert attention from addressing the broader structural issues that underline and create these food injustices. Guthman instead suggests that perhaps a better focus for societal change would be to direct the students’ efforts to eliminating redlining, invest in urban renewal, to expand entitlement programs, obtain living wages or to eliminate toxins and improve the quality of the mainstream food supply. These criticisms have asked crucial questions to furthering the political, social, and environmental justice

outcomes of AFNs. The next section introduces new directions in this movement and research.

Beyond AFNs

As these criticisms of AFN literature attest, the practice and study of AFNs have great potential for broadening both enquiry and reach. AFN scholars speak of the need to scale up AFNs from a focus on food security to consider the power relations and issues of access bound within the territory of food sovereignty, while others believe that AFNs should be scaled up from the niche to the mainstream to allow their insights and innovation to be applied to broader societal concerns. Scholars such as Wilson (2013) argue that AFNs need to go beyond “the alternative” to engage with activities of mutual aid and nonmarket exchange in non-capitalist communities. Others again argue that AFNs need to consider the implications associated with individual rather than community-led change. This movement that encompasses such a broad range of activities, degree of unity, and desire has produced a range of new terms that also go beyond the phrase “AFNs” to address these variations, which include civic food economies, community food economies, solidarity networks, autonomous food spaces, and more. So too are the practices within AFNs changing, as the emergence of new information communication technologies, such as social media and online food mapping sites, generate different points of access and reconverge relationships between producer and consumer, exchanging goods from peer-to-peer. Examples of new coalitions include the emergence of local food hubs around the world that connect rural producers with urban consumers more directly, and the emergence of i-food sharing – an offshoot of the sharing economy for food – that engages technologies such as i-phone applications to quickly exchange food within the city in novel ways.

Conclusion

Since the 1990s, a food movement has evolved to address social and environmental justice issues in

addition to economic concerns. Alternative Food Networks represent an umbrella term and body of academic literature that describe a broad range of activities that link food consumption and production in novel ways to support environmental and social justice values. By reconnecting producers and consumers in more local and direct ways, alternative food economies imply connections of trust and transparency to ensure more ethical procurement pathways. Criticisms of AFNs include the conflation of AFN characteristics, issues of exclusivity, racism and elitism, and the influence of the capitalist market on activist goals. Rather than shut down AFNs, such criticisms open up this field to further question and develop understanding of the various activities that exist under the rubric of AFNs. Alongside the emergence of new information communication technologies, our understanding and practice of AFNs is changing as they take on new forms to explore potential territories of social change perhaps toward a more ethical food system.

Introduction

Agrarianism is an ethical perspective that privileges an agriculturally oriented political economy. At its most concise, agrarianism is “the idea that agriculture and those whose occupation involves agriculture are especially important and valuable elements of society” (Montmarquet 1989, viii). Despite the fact that the “march of progress” increasingly displaces the agrarian way of life, leaving agrarianism largely anachronistic, the agrarian idyll has remained astonishingly persistent. In the contemporary United States, farmers now comprise less than two percent of the population and four out of five citizens live in either urban or peri-urban environments. Nevertheless, the constellation of values associated with agrarianism still hold astounding purchase on the American imagination. More than merely a synonym for agriculturalist, farmer, or peasant, an agrarian embraces a complex paradigm for conceptualizing and making meaning out of the agricultural experience and ardently defends agriculture’s role in society more broadly. Its disciples propose that an agrarian way of being in the world is a social, political, environmental, and spiritual good and commit themselves to preserving it.

In *Agrarianism and American Literature* (1969) M. Thomas Inge offers a comprehensive definition of agrarianism. He suggests that the essence of an agrarian outlook is comprised of five distinguishable, yet imbricated components. The first aspect is that agricultural production is conducive to cultivating not only critical food and fiber resources but also virtue. The agrarian way of life is said to engender strong morals, namely manliness, honor, self-reliance, integrity, temperance, humility, and neighborliness. Second, agrarians argue that agriculture offers stable soil upon which to stake a claim of independence through self-sufficiency and subsistence. The yeoman farmer meets most of his own, necessarily limited, needs and thus buttresses his own political, economic, and spiritual freedom.

Proponents of agrarianism also emphasize a third aspect, what might be called embeddedness. Agricultural labor provides a sense of rootedness that manifests psychologically (a psychic holism and sense of purpose and identity), spatially (a groundedness in community, region, and nature), and temporally (a connection with tradition). Embeddedness, it is argued, works to counteract the centrifugal forces of modernity that inspire fragmentation, alienation, and atomization at the expense of order and harmony. Fourth, agrarianism is antithetical to urbanism. The moral geography that situates virtue in the countryside also renders the city a fountainhead of vice, corruption, class-division, and greed. Finally, agriculturally oriented communities are believed to embody the ideal, egalitarian social order founded on affective dimensions such as cooperation, mutuality, reciprocity, and trust.

Strains of agrarianism crop up at various historical moments across the global landscape, arguably serving as the foundation for such disparate political projects as England’s Digger Movement, France’s Physiocrats, Australia’s Country Party, Italy’s Agrarian Fascists, Cambodia’s Khmer Rouge, Brazil’s Landless Workers Movement, and any number of agrarian socialist regimes. Agrarian principles also animate contemporary international grassroots movements such as Slow Food and La Via Campesina (The Peasant’s Way), to name only

two. However, as a relatively coherent and enduring political, economic, and ethical philosophy, agrarianism has been most rigorously cultivated in the United States. First as a representation of widely held values in rural culture and more recently as fertile platform upon which to express radical critique of the industrial status quo, agrarian ideals have had great reach and durability in American thought (Hagenstein et al. 2011). This entry traces the origins of agrarianism in the Western philosophical tradition, highlights key advocates of agrarianism throughout American history, underlines the ways in which neo-agrarians have mobilized the concept to suit contemporary ends, and finally explores “critical agrarianism” as an approach that problematizes the historically less savory aspects of agrarian ideology.

Agrarian Origins

Though agrarianism developed in revolutionary-era America, its seed germinated in the classical Mediterranean, nourished at the fountainhead of the western philosophical tradition. In ancient Athens the idea that agricultural activity, as the primary occupation of the predominately rural population, was shot through with political, moral, and social values positioned agrarian ideals at the very center of the civilization’s ethics. From Hesiod to Xenophon, Socrates to Plato, Greek philosophers expounded upon the advantages of husbandry and the agricultural way of life over and against alternative occupations (Hanson 1995). Here too was born the lasting association between agrarianism, democracy, and superior citizenship; as Aristotle argues in his *Politics*, “The best common people are the agricultural population, so that it is possible to introduce democracy...For owing to their not having much property they are busy...while owing to their having the necessities of life they pass their time attending to their framework and do not covet their neighbor’s goods” (Hanson 1995, xv). The virtues of agriculture as the most noble employment, fit for the freeholding, free thinking, free standing man (and it was, alas, always a man) are promoted by prominent citizens of the Roman

republic as well, notably the Elder’s Pliny and Cato as well as Cicero. Virgil’s *Georgics* and *Eclogues* take agricultural life as their central theme, sketching an enduring moral geography that positions the farmer in the virtuous middle landscape between wild nature and civilized artifice (Marx 1964). The Aristotelian concept that virtue exists at the means between two extremes is here naturalized in the dual meaning of the term, implicitly governing the way ecological experiences are understood that would have a lasting effect on the agrarian worldview.

Through the age of enlightenment, where science, technology, and the revolution of reason inspired a seismic paradigm shift in Western culture, and specifically in the perceived relationship between man and nature, the English poets continued to write in the pastoral tradition established by Theocritus and Virgil. Glorifying life in the country as a repository of traditional values, Dryden, Wordsworth, Goldsmith, Swift, and others, positioned rural life in opposition to the inherent vices of urban commercial existence. The America’s in the colonial imagination likewise took on Edenic properties as a symbolic virgin land, unspoiled by man’s folly for knowledge and material gain, populated by noble savages who lived close to uncorrupted nature (Smith 1950). Yet here at the outset a contradiction emerged between what that symbolic chastity meant to early settlers. For some it offered an Arcadian vision of redemption in primitive paradise, for others a vast fertile landscape ripe for conquest and colonization, raw materials in a howling wilderness to fuel the “march of progress.” The counterforces represented by primitivism and progress shaped the symbolic geography upon which the American experiment was established. For many in the revolutionary era and beyond, the farmer was said to cultivate the virtuous middle ground vital for inalienable rights of American democracy – life, liberty, and the pursuit of happiness.

Agrarianism in America

Before Thomas Jefferson became the patron saint of American agrarianism in the years after

claiming independence, other agrarians touted the virtues of agricultural life on the fertile soil of the nascent republic. Crèvecoeur argued in his *Letters from an American Farmer* that the independent yeoman farmer stood at the zenith of morality, closest to god, and that agriculture was the basis of national political and economic vitality. A born Frenchman turned expatriate American farmer, his *Letters* contrasted the viciousness of urban poverty and exploited peasantry in Europe with the virtuous, freestanding rural farmer. He writes, "where is that station which can confer a more substantial system of felicity than that of an American farmer, possessing freedom of action, freedom of thoughts, ruled by a mode of government which requires but little from us" (1782; Inge 1969, 53). The unending expanse of the American frontier, alongside the egalitarian bootstrapping spirit already present in the American ethos, made Crèvecoeur confident in the prospects of agrarian democracy.

But it was Jefferson who would codify the sentiments of Crèvecoeur and innumerable others into a coherent philosophy that would serve as an important keystone upon which the young republic would be built. In a famous letter to John Jay, Jefferson articulates the agrarian political sentiment in his characteristically mellifluous prose. He writes, "Cultivators of the earth are the most valuable citizens. They are the most vigorous, the most independent, the most virtuous, and they are tied to their country and wedded to its liberty and interests by the most lasting bonds" (1784; Thompson 1995, 121). Jefferson held that freeholding yeoman farmers were tied to the fate of the republic by "the most lasting bonds" because their investment in agricultural improvement encouraged them to safeguard the stability of the country and liberated them from political temptations and pecuniary interests. Nowhere is this more evident than in his succinct yet seminal 19th query in *Notes on the State of Virginia* where Jefferson outlines no less than the foundation myth of an agrarian political economy in America. He proposes that "those who labor in the earth are the chosen people of God, if ever he had a chosen people, whose breasts he made his peculiar deposit for substantial and genuine virtue"

(1787; Inge 1969, 9). Rural agriculture is said to cultivate not only essential food and fiber for the young republic but the necessary dispositions for a stable democracy free from the risk of mob rule and the tyranny of the majority (Griswold 1948). "The mobs of great cities add just so much to the support of pure government, as sores do to the strength of the human body," he warns; agriculture instills "the germ of virtue" necessary for securing "happiness and permanence of government" (Inge 1969, 10). Rather than the commercial, manufacturing economy called for contemporaries such as Alexander Hamilton, Jefferson contended that "while we have land to labor then, let us never wish to see our citizens occupied at a workbench."

Jefferson's agrarian ideology resonated with the predominately rural population, where in the early nineteenth century upwards of ninety percent of Americans were directly engaged in agriculture and buttressed the Louisiana purchase and Jackson's agriculture expansion policies. But while rural democrats were winning election, the arrival of the industrial revolution to America, with its clamorous factories and shrieking steam engines, was rousing the republic from its agrarian dream. The antebellum romantics, led by Emerson, Thoreau, Hawthorne, and other New England intellectuals, reacted to the entrance of the machine in the garden by reimagining the agrarian worldview to meet the novel conditions of the age. The middle landscape offered by agriculture, historically largely utilitarian in focus, became as never before a site of ecological stewardship in the Romantic imagination (Hagenstein et al. 2011). The political, spiritual, and psychological virtues were joined with (still inchoate) environmental benefits. Moreover, for the first time (but as we will see, not the last) agrarian ideology offered not a celebration of the status quo but something of a dissident critique to the threat of prevailing forces. As agriculture itself began to industrialize into a more extractive, commercial pursuit Thoreau laments that the machine is corrupting the virtues of the rural way of life; "the landscape is deformed, husbandry is degraded...and the farmer leads the meanest of lives. He knows nature but as a robber" (1854; Marx 1964, 258).

In romantic reckoning, the practice of agriculture remains critical but, increasingly deformed and degraded by industrialization, its merits are no longer unalloyed.

The transition from family-farming practices representative of the Jeffersonian agrarian ideal to a thoroughly commercial enterprise spurred centrally by market demand proceeded gradually over the second half of the nineteenth century. But by centuries end, the escalating tension between farming as a way of life and farming as a way of making a living erupted into two decades of agrarian dissent (Lester 2006). The counterforce manifested in both social and political ways. The National Grange strived to reinvigorate rural social life, revitalize civic republicanism, and defend traditional communitarian ideals; as one historian proposes “The Grange combined economic and social activities with educational strategies that strove to inculcate agrarian values. Family events...were designed to expose farm children to the recreational aspects of rural life, which in turn would teach that ties to family, neighborhood, and township formed the cornerstone of active, enlightened citizenship” (Summerhill 2005, 215). The social capital accrued by rural associational life translated into more overtly political insurgency as well. Aiming to confront the harsh realities of a liberalizing political economy the Populist Party gave voice to the intensifying groans of agrarian discontent. William Jennings Bryan’s famed “Cross of Gold” speech, where he reifies the primordial moral geography of agrarian sentiment – “destroy our farms and the grass will grow in the streets of every city in the country” – captures the radicalism of Jefferson’s “chosen people of god” besieged by industrial capitalism. In some respects, Bryan’s speech was a eulogy for the demise of a genuine agrarian republic.

By the first decades of the twentieth century the political power of the farming bloc had experienced its denouement but agrarian ideology continued to motivate critique from the margins of the machine – especially in regions where development had been uneven. The Nashville Agrarians, a group of depression-era intellectuals associated with Vanderbilt University, made a committed

effort to defend the cultural values that they believed sustained the South’s agrarian way of life. As the romantics had sharply criticized the entrance of the machine in the garden a century before, this group of literary-types offered agrarian ideals – political, social, economic, and moral – as dissident anchors against the national tide of capitalist, industrial expansion. The groups lasting legacy is *I’ll Take My Stand* (1930), an agrarian manifesto and an early form of identity politics that was tailored to catalyze not only mobilized regional resistance but also a widespread spiritual awakening. The manifesto exclaims “this much is clear: If a community, or a section, or a race, or an age, is groaning under industrialism, and well aware that it is an evil dispensation, it must find a way to throw it off” (1930; Hagenstein et al., 263). The pastoral, agrarian lifestyle was positioned as a corrective to the alienating and dehumanizing forces of mechanization, urbanization, and mass consumption. As Stephanie Grey (2014) reflects, “the ultimate legacy of the Southern Agrarian revolution was the creation of an aggressive agrarian heterotopia [a space of resistance providing both a refuge and a platform for critique] that animated political resistance to the industrial menace by advocating a return to a spiritual connection with the soil” (390). Looking nostalgically backwards towards romanticized ideals of self-reliance, pleasurable labor, rural community solidarity, and regional distinctiveness, the Southern Agrarians also looked forward. They laid the foundation for a new wave of contemporary agrarians who too are taking a committed stand; not (only) to defend a vanishing way of life but to embrace the emergence of a new land ethic rooted in sustainability.

Neo-agrarianism

Neo-agrarianism has come to describe the contemporary group of intellectuals, authors, farmers, and activists who are revitalizing agrarian values to meet the social, economic, and environmental needs of today. As we have seen, a normative debate of whether man and society are better served by factories or cultivated fields has

characterized much of agrarian ideology for the last two centuries. But the practice of agriculture, and its role in society more broadly, has experienced profound changes over the course of the twentieth century and the conceptual distinction between factories and fields has all but been replaced by “factories in fields.” Contemporary agrarians continue to promote one side of the industry/agriculture conceptual dyad as superior – like Jefferson, Thoreau, and the Nashville Agrarians before them – but also criticize the domination of industrialized agriculture in modernity. The unprecedented shift in how agriculture is practiced – well summed by Earl Butz’s “get big or get out” credo – alongside rampant environmental degradation of the sort that catalyzed the Dust Bowl has brought new concerns to the top of the agrarian agenda and ecology and environmental ethics now take precedence as never before.

The legacy of this line of thinking owes more to Aldo Leopold than Thomas Jefferson. Leopold was an ardent champion of environmental conservation and his “land ethic” aimed to position man into a new ontological relationship with nature. As agrarian philosopher Paul B. Thompson (2010) suggests, “For Leopold, as for Jefferson, community solidarity is a social goal that brings into focus how we are dependent on one another for the independence and liberty an individual receives from living in a free society. Leopold is especially clear that this interdependence includes the natural world” (193). The land ethic challenges an orientation – prevalent in contemporary industries such as mining, logging and indeed conventional agriculture – that perceives land in strictly utilitarian terms, as a mere means to an end of productivity, efficiency, and resource extraction. Alongside Carson’s *Silent Spring*, Leopold’s environmental ethics have had an immense impact on the environmental movement that increasingly recognizes agriculture as a central battleground. Moreover, Leopold’s holistic way of thinking about nature also profoundly influenced the “back-to-the-land” movement rooted in the radical counterculture of the 1960s and 1970s. In turn, both of these movements have had a critical impact on agrarianism as it is conceived today.

But arguably no one has had a greater influence than farmer-poet Wendell Berry. He and the myriad disciples who evangelize his gospel have brought renewed attention to age-old agrarian ideals such as the importance of living sustainably on the land and of working cooperatively and in earnest to produce healthy environments, strong rural communities, morally satisfying lives, and rewarding labor. In the *Unsettling of America* (1977), Berry criticizes the extractive nature of modern agriculture and calls for a holistic approach that respects the dignity of man, nature, and human communities past, present, and future. Like the transcendentalists before him he speaks of nature with religious reverence, proposing that “The soil is the great connector of lives, the source and destination of all. It is the healer and restorer and resurrector, by which disease passes into health, age into youth, death into life. Without proper care for it we can have no community, because without proper care for it we can have no life” (86).

Integration, connection, ecology, and community are prominent in the work of other neo-agrarians as well. Eric Freyfogle (2001, 2007) urges the development of a cultural conservation ethic which takes nature as its guide. “More than a place and human construct,” he argues, “the field is a cultural emblem of who we are and of how we understand our place. . . Here is where sound agriculture comes in: to give the world meaning, to situate us within it, to help us know how to live” (Freyfogle 2007). Wes Jackson (1980, 1996) argues for the use of appropriate technologies, perennial and polyculture cropping as part of sustainable agricultural production, and reconnecting with a community to “become native” to a place. Brian Donahue (2001) proposes that agrarians “reclaim the commons” by moving beyond the independent yeoman farmer to consider commons-oriented land use practices designed to instill an agrarian ethic and foster the social capital necessary for democratic, civic engagement. Norman Wirzba (2003) calls for an “authentic agrarianism” attentive to faith, responsibility, human limits, and cultural renewal. Each of these neo-agrarians emphasizes one particular aspect of the agrarian credo – embeddedness,

technological restraint, democratic engagement, moral integrity – without discounting the others. Alongside Berry, these neo-agrarians and myriad others are promoting an agrarian ethic sensitive to the social, cultural, economic, and environmental needs of the twenty-first century.

Critical Agrarianism

Agrarian philosophy has held striking salience in the American imagination from its nascence to the contemporary era, but there have been stringent critics of agrarianism from the outset. This critique is personified by the likes of Alexander Hamilton, the contemporary of Thomas Jefferson who pushed for a strong federal government, a national bank, and a commercially oriented economy, and William McKinley, who defeated populism and instituted protective tariffs for manufacturing, maintained the gold-standard, and instigated imperial expansion in Latin America and the South Pacific, among others. Agrarian principles were believed to be increasingly anachronistic as the United States industrialized, joined international markets, and shifted from a predominantly rural population towards its metropolitan cores. Of the prominent agrarian ideologues, Jefferson has been criticized for the inconsistencies of his stated agrarian beliefs and his actual practices as a slaveholder, politician, and culinary sophisticate. Jackson has been justifiably haunted by a racist legacy of Native American removal to open up “uncultivated” land to white farmers. The Southern Agrarians have been disparaged for technological luddism, nativist sentiment, and a conspicuous inattention to the human chattel (and later sharecroppers) upon whose beaten backs the Southern way of life was largely founded.

Moreover, as historian Richard Hofstadter (1955) persuasively argued, the practicing referent for agrarian theory was always something of a myth. Contrary to what agrarian ideologues would have us believe, Hofstadter contended that the idealized “happy yeoman” of Jefferson’s era did not choose self-sufficient subsistence agriculture as a moral high-ground so much as from a

lack of viable alternatives and limited commercial markets. What is more, he highlighted that the farm families of rural New England and the mid-Atlantic who helped establish tight-knit, small-town communities and who embraced a sustainable land ethic hardly existed west of the Allegheny Mountains where land speculation was historically pervasive: “If a rural culture means an emotional and craftsmanlike dedication to the soil, a traditional and pre-capitalist outlook, a tradition-directed rather than career-directed type of character, and a village community devoted to ancestral ways and habitually given to communal action, then the prairies and plains never had one” (43).

While there have always been critics of agrarianism, “critical agrarianism” is generally offered not by its opponents but by contemporary, future-oriented agrarians who strive to thresh the otherwise unsavory aspects out of agrarian ideology and practice. Liz Carlisle (2014) suggests that the neologism refers to those who “continually question and reshape the very category of agrarian, toward a more just and sustainable future” (2). Many of the neo-agrarians noted above would be considered critical agrarians in that they challenge the legacy of reactionary politics, ethnic/racial homogeneity, gender inequality, nativist sentiment, religious fundamentalism, and nostalgic romanticism that has intermittently colored agrarian thinking. Carlisle suggests that critical agrarians move beyond the standard appeal of strengthening ties between people and the land to ask “what kinds of ties between which people and what land? What are we exchanging? With whom? What are the boundaries or our reciprocal communities? With whom do we share? Whom do we leave out? And whom do we leave less resilient?” (2014, 4).

Radical geographer Julie Guthman (2004) is perhaps the most ardent challenger of uncritical agrarianism and unreflexive forms of localism. While neo-agrarians urge a revitalization of small-scale family farming, arguing that it will inherently encourage the cultivation of healthier food, more vibrant rural communities, improved working conditions for laborers, meaningful

ecological restoration, and expanded local markets providing access to fresh food, Guthman argues that agrarian dreams elide problematic commercial realities and structural barriers to social justice. She questions whether the expansion of neo-agrarian dispositions and practices, with their embrace of petty capitalism, limited government, and self-reliance, offers a legitimate alternative to agri-business as usual or simply a niche market accessible only to the affluent and vulnerable to corporate appropriation via token accommodations and greenwashed consumerism.

Summary

As Ross Singer (2011) suggests, and the above makes abundantly clear, “American agrarianism is a philosophical tradition and malleable discursive frame adopting, defending, revising, and reproducing mythic assumptions about the morality of farming” (345). Its malleable nature is readily apparent in the visions and revisions of each successive generation of agrarian ideologues, which of course points also towards its mythic nature, not necessarily as something that does not exist in reality but as a collective cultural representation – a persistent ideology that governs behavior and helps to frame the way individuals make meaning out of the experiences of everyday life. With deep roots in the Western paradigmatic tradition, agrarianism has evolved to take on new meanings as social, environmental, and economic contingencies arise and fall by the wayside. Despite shifts in focus through time and space, agrarian ideals have remained surprisingly consistent and agrarians to this day continue to promote agriculture, and those who practice it, as critical elements of a flourishing society. Testament to neo-agrarianism’s success is the growing number of community-supported agriculture programs, farmers’ markets, shelves devoted to food grown organically, grassroots campaigns to protect biodiversity, and urban gardening projects that are cropping up not only throughout the United States but, in an increasingly interconnected world, across the global landscape.

Despite its persistence, fundamental tensions remain salient in agrarian thought. How will the defense of tradition and the stewardship of nature be reconciled with continued scientific advance? How will conservation efforts be reconciled with neo-agrarian desires for a working landscape? How will rural independence and the ethos of self-reliance be reconciled with growing demands for collective action? How will conservative values and reactionary identity politics be reconciled with the alterity of radical critique? How will the traditional rural/urban binary be reconciled with the appeals to interdependence? How will the desire to achieve local self-sufficiency be reconciled with the pressures of a globalizing neoliberal market economy? What is clear however is that agrarians of old and new stock alike will continue to press for the cultivation of a virtuous “middle landscape” – one that is cognizant of achieving the Aristotelian means between two extremes. Moreover, they will continue to advocate for the privileged place of agriculture in an increasingly techno-scientific world. Finally, siding with Emerson, they will hold fast to the complex of values bundled in the otherwise unassuming statement, “the farmer stands well on the world.”

American Chestnut and De-extinction Ethics

Evelyn Brister

Philosophy Department, Rochester Institute of Technology, Rochester, NY, USA

Introduction

The American chestnut tree had significant ecological, economic, and cultural value to the forests and residents of the eastern United States until it was decimated by disease in the early twentieth century and became all but extinct. There are several current initiatives to make the American chestnut disease-resistant in hopes of reintroducing it to eastern forests. Chestnut de-extinction initiatives highlight a number of issues relevant to agricultural ethics, including the value of biodiversity, ethical arguments concerning genetically modified organisms (GMOs), and the concept of genomic integrity. In addition, the ethical arguments related to chestnut restoration highlight the tensions and commonalities between agricultural and environmental ethics. Ethical concerns regarding chestnut restoration pivot on questions related to whether the value placed on agricultural species is equivalent to or less than the value placed on wild species and whether there is or should be a clear distinction between wild and domesticated species.

Chestnut Blight and Recovery Efforts

Until the early decades of the twentieth century, the American chestnut tree (*Castanea dentata*) was one of the most abundant forest trees in eastern North America. Its range extended from Maine to Georgia, and it was especially prevalent through the Appalachian Mountains. Chestnuts were valued as a nut crop and as a timber source. The nuts were a reliable food source for people and wildlife, and collecting and roasting chestnuts was a shared cultural event in the region. Chestnut timber was valued because it was strong, straight-grained, easy to work, and rot-resistant. While

other woods were considered to be either stronger or more beautiful, wood from chestnuts balanced these qualities, making it suitable for a wide variety of applications, from utility poles and railroad ties to furniture and paneling. Chestnut is also the fastest-growing hardwood in eastern forests, and its economic value through the eighteenth and nineteenth centuries was significant (Freinkel 2007).

In 1904, the chestnut blight fungus (*Cryphonectria parasitica*) was identified as causing the rapid decline and death of trees in the New York Zoological Park. The blight had been imported to several sites along the eastern seaboard in infected Japanese chestnuts (*Castanea crenata*), and in spite of costly attempts at control, by the middle of the century it had spread throughout the American chestnut's range, killing billions of trees. Though not yet fully extinct, the American chestnut is functionally extinct. Very few reproductively mature trees exist. Sprouting roots continue to be fairly common throughout eastern forests, but the sprouts rarely survive to reproduce. With reproduction negligible, there is little hope for the natural evolution of disease resistance. The American chestnut is not expected to recover on its own (Freinkel 2007).

There are several current plans for assisting chestnut recovery. Through most of the twentieth century, attempts to create a disease-resistant hybrid had little success. Although the Chinese chestnut (*Castanea mollissima*) has enough resistance to allow it to coexist with the fungus, a twentieth-century USDA breeding program produced only a few plants that seemed to be disease-resistant, and these hybrids lost some of the unique characteristics of the American chestnut. In 1983, a group of plant geneticists founded a nonprofit organization, The American Chestnut Foundation (TACF), dedicated to developing disease resistance in American chestnuts and reintroducing them into eastern US forests. Using the technique of backcross breeding, TACF has developed a hybrid that is 15/16 American chestnut and 1/16 Chinese chestnut. The specimens in each generation were selected for traits that included resistance to chestnut blight along with aesthetic similarities to American

chestnut, including its larger stature and smaller and sweeter nut. These trees are in a field-testing stage, with plans underway for reintroduction to begin in the near future while further backcrossing takes place (Smith 2012).

Another recovery program, carried out by researchers at the SUNY College of Environmental Science and Forestry, is working to genetically engineer disease-resistant American chestnuts using transgenic methods. Researchers have inserted a small number of genes from Chinese chestnut species, as well as genes from wheat, grapes, and peppers into the genome of American chestnut trees. Trees in field tests have so far shown resistance to chestnut blight that exceeds that of Chinese chestnut species (Powell 2014).

The American Chestnut Foundation is also supporting research to identify surviving disease-resistant American chestnut trees and to cross them with each other. This strategy is a long shot, will take longer to produce a viable genetic line if it does succeed, and carries higher risks of reduced genetic diversity. However, it has the advantage of avoiding most of the political controversies and ethical issues raised by the other two.

Agricultural Ethics and Environmental Ethics

These efforts to restore American chestnuts to the forests of the eastern United States highlight the fuzziness of several accepted boundaries: between environmental ethics and agricultural ethics, between wild and domesticated species, and between conceptions of land managed to be wild and land managed to produce for human needs. After a quick glance at the story of the chestnut's demise and potential recovery, one might classify the case together with other contemporary recovery and restoration efforts, such as the successful return of wolves to Yellowstone Park and the contemporary effort to revive the passenger pigeon. However, while the rhetoric of those efforts revolves around wilderness and natural value, the rhetoric around the restoration of the chestnut also draws on cultural values, the provision of ecosystem services, and the trees' economic value.

So, while on the one hand the Chinese chestnut was domesticated as an orchard species, the American chestnut is a wild forest species. But, on the other hand, wild groves of American chestnuts were long managed and harvested, first by native Americans and then by European settlers (Freinkel 2007). Many of the eastern US forests that are most eligible for chestnut restoration are managed for hardwood timber production. A major contributor to restoration efforts is an energy company that invests in this effort because the species' relatively quick growth is a promising method of restoring mined landscapes and of sequestering carbon. Most of the regulatory oversight and field support for the restoration projects is handled by the US Forest Service.

The restoration effort pragmatically positions the chestnut as straddling the border between nature and agriculture. While philosophers debate whether environmental values are properly human-centered or not, promoters of chestnut restoration mobilize both anthropocentric (human-centered) and nonanthropocentric sentiments. The chestnut de-extinction effort is closely identified with other de-extinction and rewilding programs. The restoration effort also evokes a sense of nostalgia and cultural value, emphasizing the many ways that the chestnut contributed to the rural Appalachian economy, how its dependable mast production was a reliable food source in hard times, and promoting chestnuts as a wild food that might, like wild-harvested mushrooms, again become a desirable commodity.

Ethical Issues Surrounding GM Chestnut Research

The chestnut recovery program pursued at SUNY-ESF aims to provide resistance against chestnut blight by inserting genes that improve the chestnut's ability to repair damage caused by the fungus (Powell 2014). The appearance of saplings from genetically modified lines is similar to that of the American chestnut in height, crown shape, bur size, and the sweet taste of the nut.

Several characteristics of this species distinguish it from other GMOs. First, as a tree, it is

slow to grow and reproduce compared to most crops. Second, it is intended for wild release. Third, all of its wild relatives are functionally extinct. Fourth, its primary use for humans is as timber, though it is expected that people would also gather chestnuts for consumption, and regulatory requirements account for its likely use as food. Each of these unusual characteristics may have an effect on assessment of the ethics of genetic manipulation in this case. Generally, the arguments against GMOs revolve around the existence of unknown health risks, unjustified ecological risks, or undesired social impacts. Specific features of the American chestnut, including its ecological and economic context, are such that the ethical arguments for and against GMOs ought to be reexamined to take these features into account.

Leaving aside the contentious question of whether GM foods present unrecognized risks to human health, the most significant ecological risk from GMOs arises out of concern that the modified organism will mate with wild relatives or with crop landraces, thus creating gene flow that could modify wild species or traditional varieties of crops to unknown effect (Thompson 2007). In the case of the chestnut, however, the American species and its native relatives have all become functionally extinct. There are so few surviving individuals that wild reproduction is rare or non-existent. Therefore, the promoters of GM chestnut argue, if the GM research project can meet or exceed the level of disease resistance attained by traditional breeding techniques, genetic modification provides the American chestnut with its best chance to avoid extinction entirely without presenting the risk of unintended gene flow to wild populations. Proponents of using GM techniques for de-extinction purposes generally take a pragmatic view: if the desired outcome of ecological, economic, and cultural benefits can be attained at a reasonable cost and level of risk, then concerns about authenticity, historical continuity, and species integrity are beside the point.

Another ecological concern for some GMOs is that they have direct or indirect negative effects on other wild species. For instance, opponents of GMOs were concerned that pollen from *Bt* corn would poison monarch butterfly larvae. That

concern was not substantiated by later studies, but it is likely the case that the increased use of roundup pesticide enabled by genetically modified *Bt* corn has eliminated butterfly habitat by eliminating the milkweed that monarchs depend on. Again, though, this concern is rather less justified in the case of American chestnut, as the goal is to restore a common forest species to its prior range. Food webs can be expected to alter in response to chestnut reintroduction, but the speed of change is limited by the rate of restoration and the trees' own growth rate. Promoters for GM chestnut argue that the possible risks of reintroduction should be weighed against the known ecological, economic, and cultural costs of extinction (Powell 2014).

Arguments against the development of genetically modified crops also consider the possibility of negative social impacts, such as the creation of reliance on a single producer of GM seed and the control of seed sources as intellectual property. These anti-GMO arguments are weaker in the case of GM chestnut development than they are in the case of organisms like RoundupReady cotton or soy because the development of the seed source has so far been through a not-for-profit organization and university research programs which claim they do not intend to profit from the seeds. The goal of the programs is to release the seed into the wild for the sake of self-sufficient reproduction. One concern about social impact which is perhaps unique to this case is the charge that the research project has accepted funds from an energy company that causes ecological damage. As noted earlier, the energy company is funding chestnut research because of their potential forest carbon sequestration and to quickly reclaim coal-mining sites. At stake are ethical concerns about relying on tainted money – much the same concern driving the call for divesting from corporations that cause environmental damage (Jones 2014).

One further argument given against the genetic modification project is that its practical long-term success depends on the amount of genetic variation that can be introduced into the modified lineages. If there is insufficient genetic variation to ensure a stable future population of American

chestnuts, then the resources required for widespread restoration might achieve similar ends through other forest restoration measures.

Ethical Issues Surrounding Breeding Programs

While there is widespread opposition to biotechnology among the US public, this skepticism does not typically extend to the use of traditional breeding techniques to improve crops or to domesticate wild species. In this context, however, advocates of the GM project emphasize that biotechnology might be less problematic than traditional breeding, and not only on the grounds that, with some luck, genetic modification techniques may yield greater disease resistance. The central matter that is raised when comparing the traditional breeding program with the GM program is what it means to protect the integrity of the genome.

One of the arguments raised against the breeding program tracks the distinction between wild and domesticated species. The Chinese chestnut has been bred as an orchard tree, while the American chestnut, even when it received some cultivation, was not an object of selective breeding and is considered a wild species. This distinctive history can be seen in the different traits of the two species: the American chestnut is much taller, the burs are more difficult to handle, and the nuts are smaller. Some of the inserted genes come from non-chestnut species, but compared to traditional breeding techniques, a much smaller number of genes is required to confer disease resistance. The GMO program argues that an advantage of their technique is that this precision protects the integrity of the American chestnut genome (Powell 2014). Ironically, the charge of violating the integrity of a species is generally leveled at biotechnology rather than being used to defend biotechnology's benefits relative to traditional breeding techniques (de Vries 2006).

The concept of genomic integrity is intuitively compelling but not well defined. It generally depends on some type of essentialism. Typically it treats species or genomes as static natural kinds. What is problematic about the concept of genetic

integrity is that closely related plant species such as Chinese and American chestnuts are capable of reproducing in nature, even if they rarely do, and they share a large percentage of their genes. Thus, it is difficult or impossible to identify a simple criterion which separates one species from another. Moreover, artificial breeding of domesticated species and breeds routinely violates species and genomic integrity in order to improve characteristics which are of particular interest to humans. Whereas the genetically modified chestnut line includes only a small number of new genes, the backcrossed line carries about 6 % or 2000 genes from the Chinese species. However, because these species are closely related, a large percentage of their genes are likely identical or very similar (Freinkel 2007; Powell 2014).

The GM project uses the thesis that genetic modification is different in kind from traditional breeding to highlight the advantage of biotechnology's precision. This thesis is usually used to paint biotechnology as unproven and untrustworthy. However, in this context it is used to garner support for biotechnology by coupling the thesis that it is different in kind from other breeding techniques with the value distinction between the wild and domesticated. This argument allies biotechnology with a value judgment that the less intervention there is in a genome, the more genomic integrity is preserved. This argument also sidesteps the usual association between biotechnology and agribusiness by implying that even if genetic engineering has harmful social and environmental consequences in agricultural environments, in the context of de-extinction it can be used to manage wildness without domesticating it. While the breeding programs blur the distinction between wild forest and managed resource, the GM program makes use of rhetoric that maintains conceptual distance between agriculture and nature while promoting a role for technological intervention in managing nature (Biermann 2014).

De-extinction Ethics

The goal of bringing back species from extinction has raised ethical questions which can be

separated from issues raised by the particular techniques that might be used to achieve that goal. Even if a critic of de-extinction is not opposed to sophisticated genetic manipulation, there are still potential reasons for exercising ethical caution. When a species goes extinct, extinction is the result of a complicated nexus of natural and anthropogenic causes. If technology is able to circumvent those causes to reverse the extinction, critics argue, this technological rescue takes several risks. It risks replacing the power of nature with the power of technology, it risks ignoring natural history, and it risks accomplishing a deficient fix that neglects larger causes (Minteer 2014). The role that chestnut plays in this debate is to blur the distinction between restoration and de-extinction. Unlike most other candidates for de-extinction, the American chestnut is not fully extinct, its extinction was not caused by habitat loss, and its role in the ecosystem where it would be replaced is not distant history. And once again, its status as a species of agricultural and cultural value deflects some of the charge that there is an ethical penalty for exercising technological control, since agricultural species are routinely and unproblematically subjects of selective breeding and of intensive cultivation. In the de-extinction debate, as in the debate about the ethics of GM crops, the case of American chestnut restoration tests the principles at stake.

Summary

Because it blurs the distinction between wild and agricultural species, the case of chestnut breeding and GM programs presents a new test of standard criticisms of GMOs. At the same time it blurs the distinction between agricultural and environmental ethics. Because some of the newest conservation concerns and methods—such as novel ecosystems, the widespread development of ecosystem services throughout our wild and built landscapes, and the integration of wildlife habitat with agricultural lands—also soften this distinction, we can expect these questions to become ever more pressing.

Introduction

Does an American cuisine exist? The multicultural and theoretically egalitarian society of the

USA as well as its relatively recent establishment as a nation makes it difficult to identify specific foods that accurately and inclusively represent the country. It also raises other questions. What is a cuisine? Is a description of what Americans eat the same thing as a description of cuisine? Can those eating patterns constitute a cuisine? In what ways do those patterns reflect and, perhaps, even shape the history and identity of the nation? Who gets to answer these questions and why do they matter anyway?

This entry reviews a variety of approaches to the initial question, treating the definition of cuisine as a fundamental starting point. Some scholars (Long 2009; Mintz 2002) see it as a publicly recognized and officially established repertoire of ingredients, preparation styles, flavor principles, attitudes toward food, and means of evaluating taste. This repertoire represents an intentional and aesthetic approach to food as articulating the identity of that culture and is canonized through formal culinary training, fine dining restaurants, professional chefs, and cultural critics. Another approach sees cuisine as simply the culinary culture(s) and foodways of a nation – the actual practices surrounding food and eating. It is expressed in cookbooks, popular literature and media, commercial food establishments, food marketing, the overall food system (from producer to consumer) and *habitus*, and foodways in daily life. It can also be seen in symbolic meals, such as at holidays, and in tourist products associated with the nation. This approach defines a culture's cuisine, by describing its food practices.

Cuisine as a Publicly Articulated and Respected Canon

If cuisine is an officially accepted set of foods representing national identity, is it possible to say that the USA has such a canon? Most observers say no, although recently there are chefs and groups presenting new versions of older food traditions (usually, local and/or high-quality ingredients with “healthier” preparation methods). This lack of a canon reflects the history of the country as a nation of immigrants. Some romanticize this history as creating a “melting pot” of cultures in which they

all coexist harmoniously and blend into a new and unified culture; however, the plethora of cultures coming to the USA have generally been incorporated into the largely Protestant and Caucasian Western European cultures that have held political, economic, social, and cultural control since they first colonized the country. A “salad bowl,” in which individual identities are maintained, is often presented as a more accurate description as well as a democratic ideal.

There are foods (hot dogs, pizza, ice cream), food habits (shopping in quantity, outdoor grilling), and food events (Thanksgiving dinner) that seem to be shared by most Americans, helping construct Benedict Anderson’s concept of nation as an “imagined community”; however, these do not represent a unified cuisine that all Americans agree upon as representing their identity. They also do not represent a respected way of cooking, eating, and thinking about food that citizens should aspire to. In fact, the cuisines of other cultures are frequently held up as models for American foodways habits. Also, many of these foods do not necessarily require extensive culinary training or sophisticated palates to be enjoyed and are thus not considered representative of culinary arts.

Another issue in determining whether there is an American cuisine is that, until very recently, food was not part of an official public and political dialogue on American identity. There is currently much discussion on food security, food safety, and eating habits that lead to obesity and health issues in the USA, and there are social movements promoting more sustainable food systems and foodways; however, there have been no official public attempts to establish a canon of food that represents Americanness. Again, there are practices that use food to perform a national identity – politicians displaying their attempts to be one with the masses by eating certain foods (hot dogs, barbecue, fried chicken); holiday meals and foods that ostensibly celebrate the nation; and movements in the late 1800s and early 1900s to “educate” immigrants into “American eating habits,” as well as to the current popularity of cooking shows, fetishizing of culinary arts, raising chefs to star and celebrity status, and the

increasing turning of cooking and eating into recreation and entertainment as bringing food into the public dialogue; however, this dialogue does not seem to be articulating a canon of national food practices, a cuisine.

There are several venues in which this kind of discussion actually does occur. One is cookbooks and, more recently, recipe Internet sites. The first has helped construct a sense of national identity in the USA. Amelia Simmons’ *American Cookery*, published in 1796, established a definition of the cuisine of the new nation as being variations on European (mostly, British) cooking using local ingredients, preparation methods, and nomenclature. She introduced recipes using cornmeal, pumpkin, squash, Jerusalem artichokes, turkey, cranberries, and spruce beer, suggesting that American cooking was the localization of other national cuisines. Since that time, there have been numerous cookbooks either presenting American foods or that have had such a widespread appeal, such as the *Joy of Cooking* and *Betty Crocker’s Cookbook*, that they have helped to construct a shared culinary culture.

Similarly, women’s magazines since the 1940s have offered recipes and cooking and tips for procuring, preserving, and presenting food that create a shared national culture. These arguably present a national cuisine, one that in the past emphasized a heavy reliance on processed foods and new technologies in kitchen equipment. It was a cuisine dominated by the 1950s housewife concept and tied directly into American attitudes toward women, gender roles, the home, the nuclear family, and the American lifestyle as well as food. Since the latter 1980s, an industry of cookbooks, cooking shows, magazines, self-help books, Internet sites, and celebrities has helped shape a national culinary culture emphasizing the aesthetic and social dimensions of food.

These venues for public discussion raise further questions about cuisine being established by those trained and knowledgeable in the culinary arts as well as being validated by those holding power. The USA, although riddled with social hierarchies based on race, gender, region, religion, physical appearance, popularity, and more, is actually relatively egalitarian in establishing

cultural standards. Its foundation in capitalist economic theory allows the “marketplace,” the consumers, to set these standards. Anyone, in theory, can work hard and secure a place in higher social classes. They can then have a say in defining an American cuisine.

Interestingly, there are now some cultural and educational institutions participating in a national dialogue around food. In 2004, the Smithsonian Institution developed an exhibit, *Key Ingredients: America by Food*, which, sponsored partially by the National Endowment for the Humanities, traveled throughout the country, promoting discussion and thought. Similarly, starting in 2010, the SI’s American History Museum displayed an exhibit on Julia Child, replicating her kitchen and exploring her impact on American culture. Other food exhibits have been developed by museums around the country. Also, Food Studies has emerged as an academic discipline and is being embraced by educational institutions, helping develop a canon of thought and scholarship on food and the nation.

Another aspect of defining a cuisine is whether or not it is distinctive and has a recognizable identity. Elizabeth and Paul Rozin observed that cuisines could be defined according to “flavor principles,” the basic ingredients and unique combinations of those ingredients. This not only gives a characteristic taste to each cuisine but also allows that cuisine to expand and vary its repertoire as long as it maintains those core flavors.

Does the USA have a flavor principle? French theorist Roland Barthes concluded that American food is characterized by two flavors: “crispiness” and sweet. This crispiness is oftentimes achieved through deep frying, which then adds oiliness to much of the food, and by adding salt. Also, sweetness, now often coming from high-fructose corn syrup, appears in most foods, even those not thought of as being sweet, such as bread, vegetables, and meats.

Are there other aspects of American foodways habits that distinguish them from other cuisines? Are there patterns recognizable as “American”? Patterns emerge (three meals a day, emphasis on protein, historical treatment of food as fuel and nutrients, etc.), but these are representative and

common, not necessarily distinctive or unique. The existence of patterns takes us to the second way of approaching cuisine.

Cuisine as Food Cultures and Foodways of a Nation

Cuisine can also refer to the total sum of what people in a nation eat, what can also be called “food culture” or “foodways.” A cuisine then is simply the description of those foodways. This is problematic, though. A description is not a definition. Also, the multicultural nature of American history as well as the geography of the country makes such a description lengthy and complex. There are simply too many foods to include in a single description. Furthermore, identity, whether cultural or culinary, is frequently “differential,” based on contrasting with another identity. Since food in the USA has historical connections with numerous other cultures, it is difficult to identify food traditions that are distinctive or unique only to the USA.

One way to address the complexity of American food culture is to see it as a layering of all of these historical and contemporary food cultures. Folklorist Don Yoder observed that American food culture is characterized by the coexistence of layers of regional, ethnic, and popular food cultures, suggesting a way to begin describing and identifying patterns of food practices.

Every food culture or cuisine can be seen as a combination of the natural environment and the human use of and adaptations to that environment. The physical environment includes the climate, the topography, water sources, soil types, flora, fauna, and the distribution or geography of those components. These in turn shape what edibles are available naturally as well as what foods can be produced in that environment. Human interaction with that environment both shapes and is shaped by the belief system, worldview, values, and practices – the culture – of that group of people.

Such interaction in the USA has a complicated history for two reasons: the nation is geographically vast and diverse, and secondly, the human cultures interacting with the physical environment

have also been varied and have taken multiple, and often conflicting, approaches to the land and to food production from that land.

The USA is the fourth largest country in the world, stretching 3,717,813 mile². Its east coast faces the Atlantic Ocean, while its west coast faces the Pacific, and it also includes large sections of land that do not join the mainland. In between the coasts, it has plentiful freshwater resources with lakes, rivers, and smaller bodies of water totaling 181,519 mile². The climate is mostly temperate although because of its size, it reaches into the arctic as well as the tropical. It also historically contained vast woodlands and prairies with mineral-rich soils that sustained numerous plants and wildlife. It also contains desert landscapes, swamps, high mountains, deep canyons, and rolling hills.

This natural environment has translated into two characteristics of American food: seemingly unlimited abundance and rich diversity and variety of foods. Although the country has gone through times of limited food supplies (the Depressions and WWII) and there are individuals and communities suffering from “food insecurity,” the cultural ethos assumes numerous choices and enough food for every American.

The USA can be divided into four geographic regions: the Eastern Seaboard, the Midwest Interior Plains, the Western Seaboard, and the South stretching from the eastern seaboard to beginnings of the western one. Each region shares a unique combination of natural resources, Native American history, settlement history, ethnic groups, and political and economic development. Moreover, each region includes numerous subregions. These regions and subregions have their own cultural histories that oftentimes include distinctive and representative food traditions.

Can these regional foodways be taken all together to identify and characterize an American cuisine? Many cookbook writers take this approach: the excellent Time-Life series, Jeff Smith’s *Frugal Gourmet* series, and Jane and Michael Stern’s *Roadfood* collections of recipes and anecdotes from real people across the country. Folklorists and geographers also imply this approach in their ethnographic studies of

foodways traditions of specific localities, for example, Brown and Mussell’s *Ethnic and Regional Foodways in the United States: The Performance of Group Identity* and the Shortridge’s *The Taste of American Place: A Reader on Regional and Ethnic Foods*. Both explore how food reflects as well as defines the history and identity of a region but also recognize that the association of food with a place can be a relative construction based on marketing, tourism, mass media, and communal imagination. Food can function as a “rhetoric of regionalization,” being used to recognize and draw regional boundaries and invent regional identities (Brown and Mussell). Anthropologist Amy Trubek questions whether the American food system even allows for a “taste of place” since food tends to travel across the country so that its origins are rarely known. Analyzing the French concept of *terroir* (food literally tasting of the place where it was produced), she states that the USA does not have a cuisine based on regions or even a connection of food to a physical environment: “Our foodview is not informed by taste, or by place, but by the ability to purchase a consistent product, or more generally, a commodity” (p. 15). Beginning in the first decade of the twenty-first century, the locavore movement, Slow Food and similar organizations, and food systems critics and activists have begun reconnecting food and place, bringing these concerns to the general public, so that the concern itself is perhaps a step in creating a national cuisine.

The geographic regions of the nation developed into cultural regions through the adaptations of humans to those environments as well as the ways in which humans shaped the land. American history includes waves of settlement, each wave introducing new culinary practices and cultures.

The original cultural layer of American foodways is Native American, coming from Asia through the Bering Strait in Alaska between 15,000 and 13,000 years ago. These “immigrants” then spread throughout the continent adapting to local resources and developing into four distinctive regions: Eastern Woodland Cultures, Plains Cultures, Far West Cultures (including the Pacific Northwest, Alaska, and Hawaii), and Southwest

Cultures. Although tribes had their own languages, social structures, and food traditions, they tended to share a belief that humans needed to live in respectful harmony with nature. They carefully used local resources, mixing hunting and gathering with farming. Corn (maize) cultivation began around 400 AD and allowed more reliance on farming, which then leads to more permanent settlements. Corn became a staple crop, usually grown and cooked with squash and beans. These “three sisters” were integral to Native American foodways and are one of their most significant legacies.

European exploration and colonization began in the late 1400s, introducing new foods, animals, and technologies along with tremendous social upheaval and in some cases extermination. The Indian Removal Act of 1830 moved Native Americans to reservations west of the Mississippi, further disrupting traditional cultures. Many culinary and foodways traditions and skills were lost, although European settlers adapted many of them, particularly, the cultivation of certain crops of the three sisters. Native American foodways since have developed into new “cuisines” reflecting this history of disruption and homogenizing of separate cultures into one of displaced peoples. Fry bread, a flat bread of wheat flour, salt, water, and lard or shortening, is an example of a dish reflecting the experiences of poverty and disconnection with the land caused by governmental policies and social discrimination.

European settlement is the foundation of the USA as a nation, a reality that shapes its culinary culture as well as its politics, economics, and social structures. There were several waves of settlement of the USA. After the initial “discovery” by Spanish explorers in the late 1400s, the first wave occurred from the early 1600s through the early 1800s, with settlement by Western Europeans – primarily British, Dutch, and German in the 1700s. With the addition of French cooking styles and aesthetics, these three cultures laid the foundation for “American” culinary culture, setting what has been treated as the social norm for attitudes toward food – the dominant flavor and texture of the “melting pot.” The forced immigration of slaves from Africa during this time

period until the Civil War in the mid-1860s significantly influenced the Southern USA – shaping its economy, agriculture, social structures, and foodways. Spanish colonization of Mexico during this time created a culinary culture influential in what later became the American southwest.

Industrialization brought a second wave of immigration in the 1800s and also restructured the nation into rural and urban. These groups included the Irish (largely Catholic, fleeing the potato famines), southern and eastern Europeans, as well as European Jews. Although these groups came from Europe, their culinary traditions contrasted with and threatened the previously established food culture, leading to attempts to assert that culture as the American way to which immigrants needed to adapt.

The claiming of Texas and southern California from Mexico in the mid-1800s redefined Mexican citizens and their food as ethnic Americans. The California Gold Rush in the 1860s, as well as similar opportunities in the Pacific Northwest, attracted immigrants from southern China and other Asian countries as well as Russia and northern Europe. Immigration laws in the 1910s and 1920s limited the number of immigrants to the USA, shutting out some ethnicities altogether. Migrant workers from Mexico, however, were brought into the USA as an inexpensive labor force, affirming the status of Mexican culinary traditions as not only “other” but also less sophisticated and less “civilized” than “American” ones.

A final wave of immigration beginning in the 1960s brought refugees from international conflicts (Korea, Vietnam, Southeast Asia, Central America) as well as educated professionals from around the world. These immigrants introduced their own culinary traditions, expanding the foods available in the USA. Also, increased mobility, cross-cultural and cross-regional interaction among American residents, and access to global experiences have further broadened the variety of ingredients, cooking and eating styles, and cuisines available to Americans.

Throughout this history of immigration, some food cultures quickly assimilated, leading to the so-called melting pot of American culinary culture, while others retained their individual

identities, maintaining cultural forms (such as language, food, religious beliefs) and social groupings and creating more of a “salad bowl,” in which multiple culinary traditions coexist. In many instances, immigrant foodways entered mainstream American foodways and are no longer thought of as ethnic – as described in Richard Pillsbury’s *No Foreign Food*. In other cases, food provided a means for economic survival and a venue for assimilation and even public sharing of culinary traditions. Whether that sharing translated into acceptance of those ethnic identities, as Donna Gabaccia suggests, or is another form of cultural imperialism (Abrahams, Heldke) is a matter of interpretation, but it is definitely accurate to say that such cross-cultural exchange of foodways is a characteristic of American food culture (Diner, Pillsbury; Long). Be that as it may, food has often been used as a way to mark boundaries, negotiate and celebrate identity, create community, and pass along beliefs and worldviews among ethnic groups in the USA.

An additional characteristic of American food is that ethnicity – and participating in ethnic foodways – is, to a certain extent and ideally, voluntary and situational. That is, individuals can choose to highlight their ethnicity in given situations and, in some, treat it as irrelevant. This means that, in theory, an individual of Chinese heritage can choose to eat Chinese food on some occasions but not on others and can be motivated by factors other than his or her ethnicity, such as taste, convenience, expense, social setting, etc. Also, American society is literally multicultural with most residents claiming a number of ethnicities. An individual can therefore eat from multiple culinary cultures in performing their own ethnic heritage.

The final layer of food culture in the USA, and the one that is most often identified as American, is the mass-produced, commercial one that results from an industrialized food system. This system distances the people growing food (producers) from those who are eating it (consumers) by adding numerous links to the “food chain” – processors, packagers, marketers, distributors, and sellers. It depends heavily on technology and transportation, taking raw ingredients from

throughout the country, transforming them into products that are then mass marketed and mass distributed. The system values efficiency, cost-effectiveness, and profit over more intangible qualities of food. It also reflects the historical American approach to food as fuel rather than something to enjoy for itself, and it embodies other American values – quantity over quality, individual choice over communal or global responsibility, convenience, conformity, immediate and easy access to goods, and faith in human ingenuity and technology as well as a belief in its superiority and infallibility along with a sense of entitlement to abundance. Contemporary American eating habits have been shaped by the existence of large supermarkets, the choice of multiple brands of an item, purchasing in quantity and at discount, and the irrelevance of season or locale in having access to a specific food. The system has also created a national level of food culture made up of highly processed, heavily packaged, oftentimes pre-prepared foods that can be found throughout the country. Marion Nestle’s *Food Politics: How the Food Industry Influences Nutrition and Health* (2002) and Michael Pollan’s *The Omnivore’s Dilemma* (2006) heavily criticized the industrial food chain and have brought its destructive implications to the attention of the general public.

An offshoot of the contemporary food system is “fast food,” oftentimes identified by observers as a distinctively American cuisine. Eric Schlosser argues in *Fast Food Nation* that this industry reflects particular American historical conditions – the rise of the automobile, the social and geographic mobility of US residents, capitalism applied to food production, etc. Along with franchise restaurants in general, it has also homogenized American tastes and foodways and, because of its centralized top-down management model, has spread and imposed its own culinary culture throughout the country. It has also literally taken over local venues for food and established similar processes, products, and evaluations everywhere, in what has been referred to as “the McDonaldization of America.”

At the same time, the fast-food industry now recognizes regional culinary traditions and

oftentimes exploits them by inventing products simulating them and by catering to regional tastes. Sweet tea, for example, a drink distinctive to the American South, is available in many fast-food establishments throughout that region. Also, some franchises maintain their original regional roots, such as Friendly's, which started in Massachusetts and continues to serve New England style hot-dog rolls wherever it is in the country.

This layer of commercial mass-produced foods can also include a number of food-related industries and products – cookbooks, food magazines, recipe websites, food festivals and trade shows, culinary tourism, food memorabilia, and new food “destinations” and food-based events. Many of these present a de facto American cuisine by referring to “all-American” food, “comfort foods,” and foodways traditions of grandparents. Even those that present foods that are unique or different in some way actually suggest that there is a normative American cuisine. This is usually characterized as plain, straightforward, hearty, “meat and potatoes” fare that is associated with the Western European colonial and pioneer settlers. Furthermore, the system has also created a national level of foodways that are practiced and shared among most Americans.

American Cuisine as Specific Ingredients, Dishes, and Meals

These layers of food cultures can be explored through “biographies” of a particular ingredient, dish, or meal, some of which are used publicly and purposefully to signify American identity and to prove or imply the existence of a national cuisine. Oftentimes though, food takes on meaning through its usage or contexts of usage, and those meanings might not be recognized – until they either are missing or are seen to contrast somehow with another cuisine. These unrecognized foodways traditions can be seen as the actual practice of American cuisine.

Folklorists Wilson and Gillespie give an example of the raw materials of food in *Rooted in America*, in which they identify fruits and vegetables significant in American cultural history.

Some are indigenous – corn, cranberries, hot peppers, pumpkins, tobacco (not an edible but ingested in a sense), and tomatoes – suggesting another way of defining an American cuisine, but others are not – oranges, apples, bananas, and watermelons – but are widely popular in the USA and are frequently found on American tables across the country. Each of these items, however, reflects the economic, political, and social history of the nation as well as the larger food culture so that they can be said to embody American cuisine if not define it.

Similarly, specific dishes can also be “read” as presenting an American cuisine. In *Clambake: A History and Celebration of an American Tradition*, Kathy Neustadt explores the construction of meaning and identity of a particular foodways tradition in her ethnography and analysis of a community clambake in Massachusetts (1992). She demonstrates that this tradition was borrowed by Europeans from Native American foodways and has become imbued with concepts of self, nation, and community. In many ways, it represents an American cuisine through this process of adaptation, reinvention, and regrounding in the local and in the community.

Another example is barbecue. One of the most argued about food traditions in the country, barbecue is defined as a preparation method, a type of food, an event or activity, and even a condiment. It draws upon both Native American and African American heritage and has a regional association with the South but displays distinctive local variations. More subtly, it also reflects race, class, gender, ethnic, and even ethical (as in vegetarian options) identities in the USA. Similarly, in his history of Chinese food in the USA, Andrew Coe focuses on chop suey as representing the ultimate adaptation of an ethnic food to national tastes and the resulting homogenization and poor quality that has threatened the image of an ethnic cuisine as bland and tasteless. A final example of a specific dish signifying American cuisine is green bean casserole. Folklorist Lucy Long demonstrated that this casserole, although invented and distributed by a major food processing company, reflects the ethnic and industrial culture of the eastern Midwest,

where it has been adopted into family and community foodways traditions.

The quintessential American meal is Thanksgiving dinner. Officially commemorating the first harvest of the Pilgrims, the meal promotes a national identity based on Western European, Protestant colonizers and a national myth of settlement for religious freedom and harmonious coexistence with the prior inhabitants of the land. Unofficially, the holiday celebrates family, abundance, and the “freedom from want” represented in Norman Rockwell’s painting and part of the “American dream.” The meal can also be seen as representing, perhaps even constructing, national unity by offering a food event in which everyone can participate, not only sharing in certain expected foods, such as turkey, cranberry sauce, mashed potatoes, pumpkin pie, but also adding to that national paradigm individual variations reflecting region, ethnicity, ethos, class, gender, current circumstances, and even personality.

Summary

Is there an American cuisine? The possible answers perhaps just raise more questions, but the fact that it is open to discussion suggests significant characteristics of American food culture. Scholars and pundits write about it, but there are also the “de facto” constructions of a cuisine by “the people” – by restaurant owners, readers of cookbooks, chefs trying to find a niche and a name for themselves, farmers holding on to family land and financial survival either by joining one of the large conglomerates or by joining the farmers market and CSA movement, and each individual who daily makes decisions around food and, whether intentionally or not, performs Americanness through their eating.

It is also important to ask why it matters whether there is an American cuisine. It matters because having a cuisine seems to represent having a national identity that people can be proud of, that they can publicly offer to the rest of the world as well as to themselves as the best of what they are. But it also represents a unified agreement on

what constitutes that identity and what represents quality – decisions that reflect social hierarchies holding cultural power (and usually economic power) rather than the more democratic layering and blending of food cultures that exists in a multicultural nation. As Sidney Mintz points out, “. . .not having a cuisine. . .might be a price we should be happily prepared to pay for ‘what’s great about America’” (2002, p. 24).

Introduction

Definitions of rhetoric have evolved over the course of Western intellectual history. As a result, understandings of this civic art can range from the strategic manipulation of symbolic forms for persuasive ends to a constitutive process that is central to the formation of identity. In its infancy, the Aristotelian conception of rhetoric as a persuasive appeal deployed by speakers to gain the advocacy of an audience was highly influential (Kennedy 1991). From this traditional standpoint, rhetoric can be summarized as a process whereby an advocate meets an external challenge with a specific set of symbolic appeals, overcomes situational constraints, and achieves personal and communal objectives (Bitzer 1992). This narrow view of

rhetoric began to expand as a result of theorists such as Kenneth Burke, who positioned it at the center of human symbolic commerce, suggesting that it played a significant role in developing and maintaining communities by maintaining and generating new meanings that shaped perceptions of the world. Most importantly, Burke elevated aesthetic elements often associated with style in the rhetorical canon to a position of prominence alongside logic and argument. This meant representation, myth, metaphor, and narrative were central to understanding how these symbolic networks shaped identity and action. Thus, aesthetic elements such as metaphor were no longer perceived as mere ornamental devices, but were reconfigured as frameworks that shaped human perception and knowledge systems (Lakoff 1993). Here rhetoric is transformed from a civic art designed to persuade audiences into a symbolic dynamic through which those audiences are constituted. As the meanings of human experiences such as food are negotiated through these dynamics, food itself becomes a constitutive field upon which identity is both shaped and contested. Given that the constitutive negotiation of food is central to every person's experience, studies in the rhetoric of food now encompass a wide array of contexts. These investigations include, but are not limited to, the impact of certain food practices on identity, the depiction of food in political culture, the relationship between food and nationhood, agricultural myth, and food sovereignty movements' growing political resistance. Food's meaning is shaped and contested through three main processes: the mythic normalization of food production and consumption patterns, the metaphorical contestation of the meaning of food through visual and linguistic means, and the constitution of new identities that transform food into a means of political resistance.

Agriculture and Myth

First, understanding the changing meaning of food requires exploration of the role that it plays within the mythic or narrative traditions that define a given culture. These forces deeply impact

value systems and national ideologies. In the United States the rhetorical terrain of food is defined by agrarian myths that shape American consciousness. The narrative of the yeoman or gentleman farmer, sometimes historically embodied in the historical accounts surrounding Thomas Jefferson, remains deeply entrenched in the shared romantic traditions that define the relationship between farming and national ethics (Holden 2006). The value systems that are romanticized in these myths are closeness to nature, hard work, independence, self-sufficiency, and individualism. This mythic account promulgates that nature exists as a resource provided by the Creator for the farmer's benefit, an ideal later expanded in Frederick Turner's frontier thesis, one of the earliest essays defining the development of rhetorical tropes commonly associated with farming, nature, and national virtue (Smith 1950). These myths' continuing rhetorical impact can be seen in the prevalence of these value systems in agricultural regions such as the southern United States despite decreasing percentages of citizens now actively participating in food production.

These mythic systems are also points of contest. As the nature of agriculture changed in the United States during the twentieth century, these mythic frameworks came into rhetorical conflict with progress narratives that advanced a belief in technology as salvation. Classic examples of these progress myths can be seen in Pare Lorenz's 1936 documentary *Plough that Broke the Plains*, a piece of New Deal propaganda advocating for planned communities. This film and other government-sponsored campaigns challenged the yeomen myth, suggesting that technological, mass farming would bring an end to hunger by overcoming nature. The erosion of independent agrarian practices in the face of this industrial farming regime generated fundamental conflicts in the national and global psyche (Singer 2011). Evidence of this appears in movements such as the Southern Agrarians, a political and intellectual movement that warned of the dangers of mechanized farming and the threat that it posed to regional identities that were linked to the soil. These thinkers overtly objected to the progress myth as essentially dehumanizing and attempted to galvanize a

regional resistance movement by recovering the Jeffersonian myth of the small independent farmer who worked within the bounds of God and nature and did not seek to exploit the environment.

As the progressive myths of science and technology continued to expand, a new rhetoric of food emerged. This shift in food practices, as well as the methods used to normalize them, marked the primary focus of the rhetorical analysis of modern food narratives. The mythic perspective highlights how food values, ethics, and practices are maintained intersubjectively. From a rhetorical standpoint, intersubjectivity can be defined as interlocutors defining their reality through symbolic exchange. This is what is meant by normalization. Rhetorical practices accumulate and sediment over time until they become widely accepted as unquestioned ways of life (Brummett 1976). As the twentieth century progressed, agricultural products far outstripped all other commodities in the global marketplace to become the most diverse and economically important trade item in the world (Murray 2007). In one classical rhetorical enactment, the original food pyramid, the shifting rhetoric of food associated with agrarian practices is evident. While cloaked in the rhetoric of science, the mythic shift from the yeoman farmer to the mechanized food system is normalized by this visual depiction of proper nutrition. Food historians note that this pyramid has little to do with personal health but instead supports agricultural policy (Mudry 2009). The placement of grains at the base of the original food pyramid persuaded citizens to accept the new technological developments in agriculture, specifically the trend toward industrialization and specialization that mark a grain-based market. This represents a fundamental reassessment of the ways that food policies, agricultural values, and nutrition function rhetorically to generate and normalize new food narratives.

Food Metaphors

The second manifestation of food rhetoric occurs when the meaning of food itself is negotiated through metaphorical frameworks. To illustrate

this process one can examine how a particular food item can be symbolically contested through time. Communication scholars, food historians, and anthropologists recognize that the consumption of certain types of food is central to the expression of both personal and group identity (Mintz 1996; Montanari 2006). Perhaps the most coveted global commodity at the end of the nineteenth century was sugar. During the nineteenth century, consumption of foods high in sugar was a marker of status, and those who ate even modest quantities understood that this item was a luxury. As the century progressed and shifts in global marketplaces responded to the increased consumption of processed foods, sugar as a marker of status has disappeared. The diet regimes of the past few decades demonstrate that sugar has shifted in meaning from a commodity whose consumption denotes status to a nutritional toxin. This point is evidenced in the Whitehouse Taskforce on Childhood Obesity's (2010) assertions that processed foods that are high in sugar, now more prevalent in poorer neighborhoods, and constitute a threat to the health of economically deprived citizens. This metaphorical equation of sugar to a nutritional toxin has, not surprisingly, met resistance from organizations that produce and distribute sugar-based products. The Center for Consumer Freedom has been a primary mover in attempting to rhetorically challenge this view of sugar, leading to explosive political confrontations regarding the rhetorical meaning of food. The most high profile of these confrontations occurred in New York City where initiatives against large soda containers, limitations that are justified as attempts to improve public health, have been challenged in both the court system and the venue of public opinion. Here sugar undergoes yet a third metaphorical reconstruction as it is linked to personal liberty and freedom. As sugar is transformed from status marker to nutritional toxin and finally into a means for expressing individual freedom, sugar demonstrates how particular foods can be negotiated rhetorically.

A growing awareness exists that the linguistic terms to describe food have a profound impact on how the public perceives food. The publication of Upton Sinclair's *The Jungle* (1906), a novel that

exposed the unsanitary working conditions of the Chicago stockyards, provides an example of the overt use of linguistic framing devices to shift the national consciousness about food. While the work was primarily intended to initiate a national conversation about the exploitation of immigrant laborers in America, its reverberations within the food industry were more substantial. The public outcry inspired by the graphic descriptions of filth in the slaughterhouses began the age of food reformation, leading to the formation of the organization that is currently known as the Food and Drug Administration. Food companies are now conscious of the ways that images of filth, poison, or viscera can impact the marketplace and go to extraordinary links to limit what can or cannot be said about their products. Not surprisingly the management of food has generated a number of First Amendment cases in the United States (Grey 2013). Food libel laws, otherwise known as Food Disparagement Laws, have come into effect in many states. While sometimes known as "Veggie Libel" laws, cases of food disparagement usually deal with meat products. Texts such as Sinclair's *The Jungle* would likely draw a civil suit if the book were published in many agricultural states today. The most famous food disparagement controversy came in 1996 when talk show host Oprah Winfrey suggested that she would be hesitant to eat beef after hosting a show about mad cow disease. A vivid example of how food is linguistically contested through these cases appears in the use of the term "pink slime" by CBS news to describe certain methods for creating ground beef. While the metaphor "pink slime" was used in internal FDA memos to describe a product called "lean finely textured beef," the news organization has been litigated for its use of this term, which provokes disgust. Thus, the metaphorical framing devices used to describe food are now the subject of First Amendment litigation.

From a metaphorical standpoint, the terminology that divides linguistic constructs such as "natural" and "artificial" is also the product of rhetorical processes. As food is transformed from a commodity that is grown and delivered into a manufactured product, this led some rhetorical scholars to question the ontology of food

(Jacobsen 2004). In other words, delivery, packaging, and promotional campaigns impact the consumer's relationship with food, but so do the constituent ingredients, texture, and experience of eating it (Moss 2013). These foods are sometimes described as "spectral commodities" (McHugh 2010). Because these products are created in laboratories with mixtures of genetically modified organisms and artificially derived chemicals, debate exists regarding how to define these spectral products. Concerns raised about the normalization of artificial foods have increased the metaphorical contest between "natural" and "artificial" within the food sciences themselves (Nestle 2002). New linguistic terrains have merged to demarcate certain types of food that reflect particular dietary concerns. This growing linguistic consciousness is evidenced in the frequent use of terms such as "natural foods" or "whole foods" that have their origins in the organic farming movement that took root in the United States in the late 1960s. A resurgent interest in understanding how the processed food diet impacts both individuals and the environment has been the subject of a number of best-selling books (Pollan 2006). To demonstrate the rhetorical strategies of processed foods' critics, the example of vitamin fortification is instructive. Critics such as Michael Pollan argue that the vitamin fortification of processed foods such as high-sugar cereals help to normalize the existing dietary regime by allowing producers to define these products as "healthy" when they are not. Rather than encouraging the consumer to eat more "natural" foods that humans have evolved to digest, vitamin fortification encourages the perception that all food is simply a collection of artificially generated ingredients that can also be defined as "natural." Concerns about how food is being defined have led to new dietary regimes called paleo-diets that advocate a return to preindustrial nutrition patterns.

Constitutive Food Rhetoric

The third major trend in the rhetoric of food deals with the manufacture of new subjectivities that challenge existing food patterns. Recognizing

that rhetoric plays a key role in the constitution of communities by generating new meanings, many groups are now attempting to overtly create new food identities. These movements are often called food sovereignty movements. Just as discourse shapes personal identity and experience, symbolic systems also can be used to create counter-discourses that generate new subjectivities (Hall 1985). The creation of new food identities proceeds in two stages. First, the dominant strategies used to normalize certain food patterns are exposed. A good example of this process is documented in George Ritzer's work exploring the impact of the McDonalds Corporation on American consumer patterns. The rhetorical success of this one food company ushered in a new age in which consumer activity is dominated by chain stores to the exclusion of local businesses. Rather than thinking about food in terms of health and well being, consumers are being increasingly encouraged to understand food as a product that should be delivered quickly, be standardized across regions, and be efficiently offered with as little cost as possible. Thus, the rhetoric of food is deeply intertwined with the values generated by these new production, distribution, and consumption patterns. These models may be seen as natural by those who participate in them, but they are in fact products of efficiency value systems that now define and constrain human behavior by, in effect, promoting the idea that these models are natural. By making the consumer aware of the symbolic apparatus and patterns that are being used to exploit them, they are made more self-aware of the choices they make.

The second element in constituting the food sovereignty movement entails the projection of certain foods as conscious political expressions. These efforts are evidenced by the relationship between food and self-perception, as organic or whole foods become a dramatic frame of political resistance. Environmental scholars suggest that when certain foods are consumed, the consumer is increasingly making these choices as a means to express political identity (Katz 2010). While early organic advocates suggested that these diets were beneficial for their positive effects on physical health, the growing food

awareness movement looks at how certain practices express a form of political resistance. For example, while canning was once practiced as a means to allow agrarian populations to survive harsh winters, new trends show that it is now becoming increasingly widespread in mid- to upper-income households that view food preservation as a medium through which to express their personal autonomy in the face of mechanized farming (Click and Ridberg 2010). Thus, food preservation has shifted rhetorically in both its function and significance. As these practitioners become increasingly aware of human and environmental exploitation associated with the mechanized production of food, these practices have also evolved into a means for generating new rhetorically generated food identities.

Most recently food is being contested along the axis of human rights as food sovereignty movements become global in scope. These advocates draw a direct link between food and the values of individual sovereignty and freedom. The food sovereignty movement is a direct expression of these rhetorical efforts, as food giants, the most visible of which is Monsanto, are perceived to “colonize” the food chain (Lang and Heasman 2004; Paul and Steinbrecher 2003). In the face of these concerns, many corporations have become increasingly conscious of the discourse that they generate, exploring ways to project a humane, eco-friendly image that sometimes involves the use of food imagery (Cozen 2010). Understanding rhetoric as a constitutive process entails exploring how symbol systems generate ways of seeing and experiencing the world. As this growing awareness has become a global movement, new terminologies are emerging to describe this shifting subjectivity. The most resonant of these theoretical constructs has emerged from the Slow Food movement initiated by Carlo Petrini, which attempts to create a new identity that resists the fast food mentality. *Gastronomes* are defined as food consumers who consciously expand their understanding of food beyond the parameters of cost and nutrition. In particular, these consumers view food as an aesthetic, cultural, and ethical complex. In this framework the lack of self-awareness among most food

consumers is replaced by an increased awareness of both the symbolic construction of food and the broader ramifications of various food choices (Andrews 2008). The gastronome, as a rhetorical construct, represents the culmination of the shifting terrain upon which food practices are currently contested. This demonstrates the extent to which this new class of consumers is becoming aware of food as a rhetorical concept. As new subjectivities emerge to account for the shifting rhetorical environment through which the meaning of food is established and negotiated, the theoretical and critical approaches that grapple with this discourse continue to proliferate.

Summary

As American society has progressed from an agricultural to a postindustrial economy, food producers have been largely replaced by food consumers. The gulf that now exists between citizens and their food means that there are many layers of mediation between people and what they eat. Government agencies, citizens’ rights groups, corporations, and other organizations each contest the symbolic meaning of food. The process by which these meanings are negotiated, both strategically and unconsciously, is rhetorical. To suggest that food is discursively constructed means recognizing that food definitions are products of rhetoric. While aesthetic elements such as myth and metaphor may appear superficial or secondary, they are in fact the building blocks of literal meaning. Since the nation is entering a period when food is increasingly politicized, it is reasonable to expect that its meaning will undergo further transformations. Attention to the rhetorical dynamics that form the basis for how these conflicts are navigated is essential to understanding the shifting parameters of food consciousness.

Introduction

All over the world today, different peoples carry out culinary practices and methods of preparing

food that belong to and denote earlier and often particularly ancient forms of cooking (Civitello 2011). Anthropological and ethnological studies show that the cuisine of our ancestors is far more than a long-standing system of preparing food developed down through the ages. Bio-archaeology and ethnobiology also reveal that the cuisine of our ancestors is not a simple cluster of remote culinary habits or customs but involved special artifacts, technical expertise, and basic skills related to nutrition and environment. Moreover, it reflects archetypical images and ideas about the origin and identity of individuals and groups. In addition, traditional concepts of gender are embedded in the most ancient culinary practices. Ancestral cuisine is also a mirror of the economy and the resources of a territory and is a document of the political history of a community, its social hierarchy, and distribution of power through the centuries. But first and foremost, ancestral culinary practices have an anthropological and cultural dimension. They reveal spiritual and material beliefs in nature and the relationships between humans and other creatures (Kiple and Coneè Ornelas 2000). In many cases, the most ancient culinary practices have evolved into cooking rituals rather than simply systems of preparing food. What makes a remote culinary method ritualistic is not just a habit, albeit regularly and invariably followed by peoples on certain occasions or in precise contexts. Yet, a long-standing practice of preparing food becomes a cooking ritual if it is related to or carried out as a solemn rite, that is to say, an official ceremony consisting of a series of actions performed according to a prescribed order with a precise cultural meaning, whatever it is. So “ritual” is a collective term that designates the range of techniques that peoples use to capture or promote life, fertility, prosperity, health, etc. (Pilcher 2006). There is no science or discipline specific to ancestral cuisine and cooking rituals. Many social sciences deal with this field: e.g., anthropology, ethnology, archaeology, history, linguistics, sociology, theological studies, and so on. Indeed, many methods and approaches help us to understand how people conceive and develop cooking practices relating to their cultures (Mintz and Du

Bois 2002). Interviews and participant observations are two primary methods, as well as archaeological and ethno-botanic researches. In addition to empirical data, popular mythology, epic, and historiographical literature shed light on the cuisine of our ancestors and their cooking rituals. Besides, the food lexicon of peoples is a depository of knowledge of utmost importance. Culinary traditions are investigated by sociology, especially with regard to spiritual, moral, and political dimensions. Further important data are brought to light by cross-cultural comparisons. All these researches show that the attitudes toward the cuisine of our ancestors and their cooking rituals not only are a mirror of archetypal beliefs and shared convictions but also reveal and perform a critical function.

Food Preparing as a Biological and Cultural Practice

From a historical perspective, the first appearance of ancestral cuisine occurred in prehistorical food rituals (Toussaint-Samat 2009). The analyses of these rituals are philosophically instructive insofar as they show that ancestral cuisine is not a mere relict of our past and that cooking is far more than a biological necessity and an instinctive practice. Prehistorical food rituals disclose that activities involving food had a theoretical dimension. There is no doubt that from the earliest times, culinary practices were strictly dependent on the resources, materials, and techniques at hand. On the other side, culinary tastes and social and cultural occurrences also play a role in the evolution of cooking. One of the most significant rituals among primitives was offering human flesh to deities. And cannibalism was not only a ritual but also a natural response to any severe food shortage. Prehistorical food rituals show that the adoption of techniques to prepare and process food comes from the interplay of technical and economic restrictions as well as culinary tastes and aesthetic or social standards. A good example is the prehistorical and historical Arctic peoples cooking sea mammal meat and extracting the oil by boiling according to special recipes. As this

example shows, creating recipes and inventing cooking methods to make food edible were not simply technical issues, but expressions of human artistry and inspiration. More in general, ancestral cuisine represents the cultural heritage of populations and especially the natives of a country. Indeed, the 2010 declaration of Mexican cuisine as an intangible cultural heritage in compliance with the UNESCO Convention for the Safeguarding of the Intangible Cultural Heritage has great significance. The award – the first for food – recognizes Mexican cuisine and in particular Michoacán cuisine as an integral part of an ancestral cultural system characterized by wide social diversity and geographic biodiversity. These days in fact Mexican dishes are still based on native foods and culinary practices, as *nixtamalization* and *chinampa* demonstrate. The award is a sign of the social, economic, and ethical issues existing in contemporary societies about preserving ancestral foods and practices. In the most recent philosophical debates, ancestral cuisine is seen as a public good and a keystone of the common well-being of multiethnic and multicultural societies. Along this line, many public policies are based on the assumption that preserving ancestral cuisine is a way of recognizing native peoples' identity and respecting differing cultures, attributing each its own dignity.

Art and Religion: The Spiritual and Symbolic Dimensions

It is often debated whether ancestral cuisine is related to the spiritual/mystical dimension. Many studies have pointed out that the dividing line between cooking and religious rituals is not clear-cut. And the same may be said about the relationship between cuisine and art, given that food prepared according to cooking rituals is surely an artifact. Some dishes are even authentic artworks: in Korea rice cake are prepared with azalea flower petals to celebrate the beginning of spring or shaped like the sun, moon, stars, and earth as a prayer for good weather (Yeun ja 2010). According to some, cooking is itself a form of art and cooking rituals belong to religion and beliefs

in the supernatural. This contains a grain of truth, though it seems to lay stress exclusively on one feature of a multifaceted phenomenon. Striking evidence of the spiritual as well as physical dimension of cooking can be found in the Ancient Greece *mageiroi* and their ways of preparing food (Berthiaume 1982). From ancient times ancestral culinary practices have been related to religion and art, as ancient food ceremonies and sacrifices to deities demonstrate: e.g., Greek festivals like *Thesmophoria* and *Karneia*, the Jewish cult of YHWH, and Confucian ceremonies and sacrifices. In other words, cooking, religion, and art are separate spheres of human activity involving complex relationships. Accordingly, a reasonable view is to consider cooking not just as a material habit, but as a practice entailing spiritual convictions and revealing the mystical or, more properly, the symbolic dimension of food. So, in Ancient societies activities involving food were conceived as practices that enter the divine realm, and cooking was a daily practice with extra-material implications. This is a literary leitmotif and in particular a general theme running through epic poems, such as the *Odyssey* and *Iliad*, and comedies, such as *Dyscolus* by Menander. Food rituals that are genuinely ceremonies such as Japanese Way of Tea are philosophically instructive. This rite symbolizes the purification of the participants and creates a metaphorical relationship between the physical space where it is enacted and the cosmos. Taboos also confirm the symbolic power of food. In ancient cuisine a common rule was to avoid particular foods until sacrifices were performed. During sacrificial rituals, humans fed and communicated with their ancestors living in a supernatural realm, and once the spirits had finished eating and drinking, humans could not waste the food, but had to share it out for consumption. Some good examples are the *Hyakinthia* culinary rituals in Sparta and the Pythagorean and Orphic culinary customs. As well known, meat provides the most striking taboo in antiquity. Yet, in ancient Egypt, beans were treated with the same awe because of their association with the soul's transmigration. Nowadays, in the Indonesian island of Sulawesi, the nobility and their serfs are strictly forbidden

from eating white buffalo, great river eel, and white chicken because their mythical ancestor, Tana Toraja, had united with a water sprite of the Sa'dan river. The close relationship of food with mystical/spiritual ideas is patent, especially where recipes are institutionally cooking rules and religious precepts. The Jewish Kosher food is an emblem since cooking instructions (*kashrut*) are contained in the Talmud. According to Jewish tradition, cooking is not simply nutrition, but, like religious rituals, a path toward a richer extra-material sphere. The symbolic dimension of cooking is well depicted by many ceremonies and feasts such as *Rosh Hashanah*, the meal preceding Yom Kippur, Sabbaths, weddings, funerals, etc. At *Chanuka*, it is common to fry pancakes in oil in memory of the miracle of the Maccabean revolt. At *Tu B'Shvat*, fruit representing spring is served in addition to *kanape*. At *Purim*, *Hamantaschen* cookies are prepared to recall the episode of the Book of Esther where Haman plots to destroy the Jewish community in Persia. At *Shavuot*, which commemorates the giving of the Torah at Mount Sinai, cookies are baked in the shapes of mountains and Torah scrolls. Cleaning rice is one of the most difficult ceremonies performed during Passover, when on the first night, Jews take part in a ritual meal in which the story of the Exodus is recalled with *matzah*, the unleavened bread of affliction.

Anthropological and Social Implications

Food preparing concerns theoretical issues related with personhood and fundamental anthropological and ethical questions, to begin with the essential values of life and death. Cooking rituals teach us how food preparing is related to human nature and the view of our ancestors about humankind and the survival of the race. Traditional food ceremonies, such as Mexico's Day of the Dead Ceremony, are in many cases a heritage of native ancestral rituals incorporating those of immigrants and conquerors, and thus, they are a privileged viewpoint for a more general inquiry into the concepts of life and death (Brandes 1997).

The use of food offerings placed on graves or adorning home altars or idols are an important way to put the living in touch with the dead. This shows that peoples conceive food rituals as symbolic ways to communicate with their lost ones. Such offerings invariably include starchy foods, either savory or sweet. A famous example is the Portuguese *folar*, an ancestral food symbolizing solidarity and brotherhood. In Ancient Greece, the practice of offering bread or sweets to deities and preparing cakes for public celebrations had both a collective and individual significance. It is meaningful that cooking rituals related to death and life involve sweets and starch. As these foods contain glucose, an important energy source, bread and sweets offered at death ceremonies are expressions of life, vitality pleasure, and richness. Another ethical and social issue involved in cooking rituals regards differences between the genders and, conversely, equality between female and male (Goody 1982). The assumption that food is related to women is embedded in the history of ideas of many cultures, starting with the Western matrilineal structure. Firstly, ancestral cuisine is related to the mother role in the construction of families and communities. And then biological, social, and cultural elements all point to deep connections existing between cooking rituals and procreation. In many cultures, the kitchen is the place where social and gender relations are shaped. This displays the creative dimension of cooking and the intimate unity between body and mind embedded in activities involving food. The emotional and social dimension of cooking is well illustrated by Bangangté traditions and their idioms regarding procreation and gender division (Feldman-Savelsberg 1995). Among this Cameroon population, wives stay in the kitchen most of the time and welcome the guests either there or outside in the yard, while the other rooms are the realm of their husbands. Though Bangangté women no longer give birth in the kitchen, they continue to consider gestation as a long cooking process and talk about the full-term fetus as "cooked food" or "porridge." Men refer to sexual intercourse as "tending the fire." In the Bangangté view, the continual mixing of procreative fluids (water/sperm and oil/blood)

produces a smooth and tasty meal (a healthy birth). Accordingly, Bangangté women describe their feelings about their swelling bellies like the smell of cooking maize. A double connection between cooking rituals and the human attitude toward the values of life and procreation lies behind these ideas. Firstly, ancestral cuisine reflects our gender relations and convictions about the sexual sphere and social status of persons; besides, many cooking rituals associated with human sexuality and fertility are not only aesthetic rituals but also practical tools to implement a precise social and gender structure. Ancestral cuisine is a precipitate of our way of thinking and living together, and, furthermore, it is an artifact that concretizes desires and aspirations about social status. So, it is significant that food offerings are of paramount importance in many child-naming ceremonies where certain foods are offered to the infant as symbols of purity, power, health, wealth, and prosperity. The broad idea is that we are what we eat and that our lives and social roles are reflected in what and how we eat, an idea which is present in mythology and many idioms too. For instance, water and rice are the basis of ancestral cuisine and many cooking rituals, and in some idioms or myths, eating rice mirrors being and water denotes the power of plants and animals. Furthermore, ancestors are sometimes seen as seminate spirits growing from water (Bloch 1985). Cooking rituals are also a testimony of the historical coexistence between peoples belonging to different cultures and are a way to promote dialogues. This is not a proposal but a historical experience, since nowadays many national cuisines display this mixture of different culinary practices. Some experiences demonstrate that cooking rituals are able to overcome social and moral conflicts and divisions, and so they represent a powerful force to create a common background across populations. The Mediterranean cuisine is an outcome of the interplay of different culinary and cultural traditions. Around the Mediterranean sea, Christians, Jews, and Muslims today prepare and eat similar dishes based on fish, poultry, and eggs for marriage feasts, funerals, and other special occasions.

Politics, Ethnicity, and Identity

Processing food has many ethnical and political implications concerning identity and reciprocity among people and political authorities (Flandrin et al. 1999). In many societies cooking rituals are instrumental to political aims or are the symbols of special political powers. Peoples ascribe to ancestral food customs political meanings, too. Especially among immigrants culinary lexicon and cooking practices are a symbol of their communities' history and a reminder of their homeland. For instance, nowadays spices are largely used and carefully preserved in pouches to recall the forced Atlantic passage back in the slave trade. Moreover, to exchange food or to eat together, the same food according to a rite is a way to express trust and loyalty or manifest consent. Eating from the same cooking pan may denote a strong sense of fellowship; conversely, eating some kinds of food or someone else's dish may mean the opposite. In some cultures, there is the use of sharing food with relatives and neighbors in memories of ancestors. That can be also a sign of distinction and exclusion. Ways of processing food were introduced by political authorities in order to distinguish the culture of the land from foreign ones and in consequence build a distinct national identity. Moreover, to adopt a cooking ritual can be interpreted as a privilege of a class or group. As well, cooking rituals may be adopted to support a political primacy. Food ceremonies can also celebrate political powers within a community or the domination of one group over another. With the Incas *chicha* was associated with imperial power: the city of Cuzco was also called *Akhamama* which means "*chicha* mother," and *akhamama* is the fermenting agent used to brew *chicha*. Hence, *chicha* mother is a metaphor for the role of Cuzco in Andean politics. Iconic dishes are also powerful signs of national identity. This is well illustrated by the Vietnamese *Bánh Tét* prepared at *Tết Nguyen Dan*, the ceremony that celebrates the origin of sunlight. The entire cuisine of some populations is ritualistic and based on archetypal foods: Japanese cuisine and its rice culture are emblematic. From these experiences we see that the meaning of cooking rituals for a community

may change, according to the political and historical context. To recall the cuisine of the ancestors may have positive or negative connotations and effects with regard to present politics. Especially for those ethnical groups that suffer exile or persecution, cooking rituals refer to the past and, hence, express acute feelings of nostalgia. Alternatively they can express desire for peace, but even revenge. Legends about the lands and the foundation of the nations or about the origin of an ethnic group are sometimes embedded in ancestral cuisine. Nowadays the renewal of cooking rituals of our ancestors often conveys deep ideas about political powers among the peoples, and it is a way of conserving basic political conceptions about government and/or perpetuating traditional attitude toward democracy or aristocracy and/or the role of man and women in the public sphere. Ancestral cuisine shows that identity is a value which can be considered from both a collective and individual point of view. This is true especially when cooking rituals, such as Andean's *entrada*, are symbols of the identity of an ethnic group. Such collective practices in daily life or special ceremonies can assume more profound significance to individuals too: preparing and eating together dishes made of native ingredients may evoke mutual recognition (Hastorf 2012). In cooking rituals politics is frequently mixed with religion. In many cooking rituals pleas to political authorities are mingled with manifestation of gratitude to deities. Nowadays, in West African agricultural economies, indigenous cooking rituals based on the yam are a way to recall flourishing ancient clans and kingdoms. In some areas they are still an occasion for tribes to pay tribute to the king and gods in memory of their ancestors. In many Pacific archipelagos, first fruit ceremonies are based on yams, and they are typically associated with chiefship and ancestral deities. With its seasonal lifecycle, the yam is the fulcrum of the calendar and diet but is also a cultural icon. At the *i sevu* festival, new yams are offered to the gods and shared among the people to promote health and prosperity for the community. According to tradition, Fijian villages are an association of kin groups that claim to have separate ancestors. Thus, sharing food indicates solidarity and can

also mediate political tensions (Turner 1984). Furthermore, ancestral and ritual culinary practices can be evocative of the social hierarchy and political organization of a community. Food activities may define the relationships and the status of individuals within the community as well as between communities. Customs in Sulawesi are a good example. At the king's funeral in 1969, the Makale nobility were plied with a meal based on pork, rice, and betel to renew ancient feudal obligations. All the king's food and everything concerned with it are kept apart, even from his closest family. Food and political patterns are often metaphorically associated. In the ancient Chinese Laozi doctrine, it is common to compare governing the state to frying small fish. Cooking rituals are in some cases a real political practice, so that even the civil service and the education system for the top cadres include learning culinary techniques and food rites. Finally, foods can be icons of political and/or social institutions. In some cultures eating in compliance with a precise rite becomes a distinctive feature of civilized people. Some communities have developed a hierarchy of social status based on food taxonomies. As is well known, in many societies cereals were and sometimes still are emblems of the public ceremony officiating marriage as the basic institution of the society.

Summary

Ancestral cuisine is neither just a form of art nor a relict of the past. On the contrary, by exploring ancestral culinary practices, we can understand that food preparation is a multifaceted phenomenon and a complex human practice. It has a great philosophical significance since its implications on our life are far from being transitory and purely material (Curtin and Heldke 1992). An inquiry into ancestral culinary practices is a good way to reflect about the relationships existing between our physical needs and our minds insofar as the body is inextricably connected with emotions and ideas about human nature. In addition, cooking rituals are habits shaped by cultures and spiritual/religious/mystical ideas. Food ceremonies often

show beliefs on personhood and conceptions about the self and others or about the relation of humans with nature. Ancestral culinary practices reveal moral and social convictions and show that preparing food may be an activity involving implicit values. Ancestral cooking practices rely on archetypes about the gender and self-identity of peoples and are a testament to the political history of a community and its social hierarchy. They also reveal the role played by natural resources and the environment as well as technical expertise and nutritional factors.

Introduction

Agriculture and wild food harvesting impact the welfare of humans and other animals in many

ways. The total impact on welfare varies according to the foodstuffs in question as well as the methods of production or harvesting used. Just as different lifestyles have different sized carbon footprints, different diets have different sized welfare footprints or total negative consequences to the welfare of sentient humans and nonhuman animals. Because every diet has a welfare footprint, the salient questions concern the size and moral salience of welfare footprints. This entry surveys the connections between human dietary choices, agriculture and other forms of food procurement, and welfare footprints, particularly as they pertain to nonhuman animals.

The Concept of a Welfare Footprint

In an increasingly globalized, industrialized, and urbanized world, many people are becoming more aware of the impacts which their consumption of goods and services has on the welfare of other human and nonhuman animals. The result of this increased cognizance of welfare footprints is that many people change their patterns of consumption in order to reduce their welfare footprint.

While the term “welfare footprint” is newer and lesser known than terms such as “carbon footprint” and “ecological footprint,” the underlying concept is similar. Blood diamonds, for example, are a widely acknowledged example of the core concept of the welfare footprint for a nonfood good. These diamonds, also known as conflict diamonds, are mined in conflict zones and used to finance military insurgency, destabilizing regimes causing loss of life, including through the forcible use of child soldiers. Some would-be consumers opt not to purchase diamonds at all in response to the problems of diamond extraction and trade. Some players in the diamond industry are attempting to reduce the welfare footprint of diamonds by producing conflict-free diamonds. The Kimberley Process Certification Scheme is one such attempt.

Another familiar example illustrating the concept of welfare footprints, also concerning solely humans, is coffee production. The coffee market can be volatile, and small farmers can have

difficulty competing on price alone against industrialized operators. While subject to various criticisms, fair trade coffee aims to produce coffee without the exploitative use of low-wage farm laborers, as is common in the tropical regions of the world where coffee is produced.

Coffee production also offers an example that helps transition to the welfare of nonhuman animals. Shade-grown coffee is a system of coffee production, which intersperses coffee shrubs with trees in order to provide habitat for wildlife, particularly birds in coffee plantations. Coffee is often grown in mountainous regions once covered with upland tropical forests possessing immense biodiversity, and so shade-grown coffee is a form of environmental remediation and habitat enrichment for endemic and migratory wildlife. The Rainforest Alliance offers certified shade-grown coffee and is endorsed by the National Audubon Society for its positive impact on migratory bird populations.

Food and Welfare Footprints

Having discussed some common examples of nonfood products illustrating welfare footprints, the connections between food and welfare footprints remain to be discussed. Many consumers now recognize that the welfare of nonhuman animals is impacted by the products they consume, especially food. The total impact on nonhuman animal welfare, both on animals directly consumed and on animals otherwise harmed in agricultural production or wild food harvesting, varies considerably depending on the foods one chooses to eat and how these foods were produced. Granting that animal welfare is morally significant, the size of one’s welfare footprint is morally salient and dependent on what one eats.

A number of complex factors enter into determining the welfare footprint of various. There are three distinguishable ways in which animals’ welfare is impacted by food procurement. These will be discussed in turn.

The first, perhaps most familiar way is in which animals raised for human consumption are treated. Living conditions and treatment from

birth through slaughter constitute this potential contribution to a welfare footprint.

The second way involves animals harmed during animal agricultural production or the harvesting of wild animals yet not eaten. This includes accidents, bycatch, disease, and culling. A prominent example of culling occurs in chicken egg-laying factory farms where male chicks are simply discarded at birth because their lives are useless for egg production.

A third way involves animals harmed in the production or harvesting of food to be fed to humans or other animals. For example, aquatic animals are harmed to produce fishmeal used to feed captive fish that are raised for human consumption. Less discussed are harms to field animals resulting from plant agriculture such as corn for human consumption or animal fodder. Even diets free of animal products have welfare footprints in the form of harms to these field deaths. This issue is discussed further below.

Indirect harms to other animals resulting from animal agriculture are more widespread, however. The Food and Agricultural Organization (FAO) of the United Nations concludes in no uncertain terms that “the livestock sector emerges as one of the top two or three most significant contributors to the most serious environmental problems, at every scale from local to global” (FAO 2006). The ripple effects of animal agriculture on wild animals and the broader environment are immense, perhaps incalculably so, yet also contribute to the welfare footprints of diets containing animal products.

Animal Agriculture and Human Welfare

Animal agriculture also has costs in terms of human welfare, both of workers and of those in surrounding communities. The negative effects on humans, which contribute to welfare footprints, are particularly high for industrial animal agriculture. Upton Sinclair’s classic 1906 novel *The Jungle* portrays the conditions in which early twentieth-century immigrant laborers worked inside meatpacking facilities on Chicago’s stockyards. Although *The Jungle* is fiction, Sinclair

worked undercover in the industry for several weeks to gather information in order to accurately portray working conditions inside slaughterhouses. The president at the time, Theodore Roosevelt, was so disturbed by Sinclair’s novel that he ordered an investigation into the meatpacking industry. This resulted in the 1906 passage of the Pure Food and Drug Act and the Federal Meat Inspection Act. The regulatory body associated with enforcing these acts is now known as the US Food and Drug Administration (FDA).

In the United States, there are approximately 700,000 workers employed in Concentrated Animal Feeding Operations (hereafter CAFOs), colloquially known as factory farms. A further 500,000 workers are employed in the slaughterhouse and meatpacking industry. These workers are predominantly immigrants and people of color. Thirty-eighty percent of these workers were born outside the United States. Fast line speeds lead to injuries and repetitive manual labor leads to overuse injuries such as carpal tunnel syndrome.

The quality of life in surrounding communities is also affected by factory farms from the copious amounts of excrement they produce. Manures transmit more than 40 diseases to humans, including *E. coli*, fecal coliform, and Salmonella. North Carolina has ten million hogs, which produce twice as much excrement and urine annually as the human populations of Chicago, Los Angeles, and New York combined. This waste is stored in large lagoons or sprayed, untreated, on adjacent fields. The stench can be unbearable and the hydrogen sulfide emitted can cause flu-like symptoms and brain damage. Water contamination also results. Livestock are a major source of nitrate pollution in groundwater, which is linked to spontaneous abortions and infant mortality. Runoff and catastrophic lagoon failures pollute streams, rivers, and lakes causing eye infections and leading to algal blooms of the dinoflagellate *Pfiesteria piscicida* which have killed tens of millions of fish in the United States and cause acute skin burning, cognitive impairment such as memory loss and confusion, gastrointestinal, and other symptoms in humans (EPA 2001).

Animal Death and Animal Welfare in CAFOs

The number of land animals raised and slaughtered for food in the United States has varied between 8.9 billion and 9.5 billion annually from 2000 to 2011. When sea animals are also taken into account, the number of animals slaughtered annually increases to approximately 30 billion. In what is perhaps the most complete estimate of the total number of animals died annually to feed Americans, Noam Mohr calculates that 63 billion animals died for the American palate in 2011. This figure includes animals killed but not eaten such as animals which are converted to fishmeal and “discarded” male chicks from egg-laying operations, but notably does not include field deaths resulting from the cultivation of animal feed. Mohr calculates that the average American’s diet equates to the death of 1/8 of a cow, 1/3 of a pig, 5/6 of a turkey, 25.5 chickens (including 1.5 for egg production), 43 fish, and 134 non-fish aquatic animals each year. This amounts to 16,000 animals per American when extrapolated over a lifetime (Mohr 2012).

Global meat consumption has increased dramatically in recent decades as has the exportation of factory farming techniques from the United States to countries abroad. Annually, approximately 53 billion animals are killed for consumption worldwide. Since 1950, worldwide consumption of animals has increased five times.

In addition to the number of animals killed, the size of the animals one eats is also a factor in welfare footprints. For example, if one were to eat solely chicken rather than beef and assuming that the chickens and cows were reared in similar conditions such that they had similarly poor welfares, one’s welfare footprint would be markedly larger because the number of chickens needed to fulfill one’s nutritional needs would be much larger than the number of cows needed to produce the same quantity of food. To quantify the issue in 100-g serving sizes, an average sized cow of 1600 lb. at slaughter before processing yields approximately 1000 servings, a 300-lb pig yields approximately 650 servings after processing, and an average sized so-called “broiler” chicken weighs approximately

5 lb. yielding around 12 servings. Since a person’s nutritional requirements are largely stable over time, and animals of different species differ in size by many orders of magnitude, a conscientious omnivore concerned with reducing his/her welfare footprint minimizing the number of animals he/she consumes could tailor his/her meat consumption accordingly (MacClellan 2013).

The conditions in which animals are raised and the manner of their deaths are essential aspects of a diet’s welfare footprints. The vast majority of chickens, pigs, and turkeys raised for food in the United States spend their entire lives in CAFOs. Most cattle spend their final weeks in CAFOs for “corn finishing” as well. Increasingly, fish such as carp, tilapia, salmon, and grouper are raised in aquacultural CAFOs. Shrimp and prawns, invertebrate animals, which may be sentient, have been aquacultured since the 1970s.

Animal welfare in CAFOs is extremely low compared to relevant alternatives and is likely sufficiently low that lives lived in such conditions are lives not worth living. Factory farming has been condemned from a wide variety of moral perspectives, even by Pope Benedict XVI, religious authority to a tradition which believes that humans are categorically superior to all other animals and granted “dominion” over them. The welfare footprint of a diet containing factory-farmed animal products is invariably larger than a diet not containing animal products produced in factory farms.

Introduction

Animal boredom is an unpleasant state experienced by animals in monotonous environments, which can pose a serious threat to animal welfare. It is common parlance to say of animals that they are bored. Alex the grey parrot, according to an oft-cited example, gave nonsensical solutions to puzzles if these puzzles were monotonous or if the order of puzzles reverted to simpler, less challenging tasks – it seems that he was bored (Burn 2017). It has however been controversial whether animals can be bored, and the science of animal boredom is

still in its fledgling stage. Animal boredom should however be taken seriously as a harm imposed on animals. This article explores notions of boredom in philosophy and social science, discusses empirical approaches to animal boredom in ethology, and identifies ethical issues surrounding the topic.

Boredom in Philosophy and Social Science

Distinctions Between Types of Boredom

Philosophers generally converge toward the view that “boredom” is an umbrella term for several different phenomena. Most contributors to the philosophy of boredom draw a distinction between a more ordinary “situative boredom” and a more elaborate “existential ennui” (which traces back to Heidegger’s notion of “deep boredom,” Heidegger 1983). Situative boredom is what one experiences when pursuing an understimulating or monotonous activity, often linked to an unpleasant feeling that “time drags.” When philosophers discuss situative boredom, it is usually made out to be a certain kind of unpleasant emotion or mental state associated with a lack of interest. O’Brien (2014) proposes the analysis that boredom is crucially “an unpleasant mental state consisting of weariness, restlessness, and lack of interest” (O’Brien 2014, 236). Existential ennui is a perceived lack of meaning in life or a troubling awareness of the absence of desires (see, e.g., Svendsen 2005; cf. Heidegger 1983). Existential ennui is sometimes argued to be an essential part of the human condition (Svendsen 2005, 12; Heidegger 1983, 111). Situative/existential distinctions have helped popularize the view in philosophy that animals can experience a certain primitive (situative) boredom, but only humans experience a more profound and philosophically more interesting (existential) boredom. Philosophical discussion has then focused on existential boredom, tacitly assumed to be exclusively human. Despite its name, “situative” boredom can last for long and recurring periods of time, in which case it is called “chronic boredom.” The study of human boredom has been a topic for sociology and psychology, primarily as the study

of boredom in the workplace and during incarceration, as well as boredom proneness as a character trait or an indicator of character traits (cf. Fisherl 1993; Farmer and Sundberg 1986). The distinction between existential and situative boredom, though important in the philosophy of boredom, is not typically found in empirical research.

Animal Boredom

The existential variety of boredom is widely thought to be impossible for animals to experience (Svendsen 2005, 32; Doehlemann 1991, 132), mostly because animals are assumed not to be aware of any meaning of their life, or the lack thereof (though this view has been challenged by Wemelsfelder 2005). Nor are animals presumed to be capable of the awareness of an absence of desires. By contrast, there is nothing in the characterization of situative boredom that would make it impossible for at least some nonhuman animals to experience it. No doubt many captive animals are capable of being weary and restless and of lacking interest in activities and objects in their environment. This coincides with the views of most philosophers, who typically have no doubts that many animals can experience situative boredom, including chronic boredom.

Empirical Approaches to Animal Boredom

Notions of Boredom in Ethology

The first calls for a scientific investigation of boredom in animals were uttered in the 1980s (Wemelsfelder 1985). Since the interest in animal boredom stems primarily from animal welfare science, the focus lies on boredom's most harmful form, chronic boredom. The two main contributors to the theory of animal boredom, Wemelsfelder and Burn, agree that boredom is an unpleasant state, caused by monotonous activities and environments, connected to the feeling that time drags. They differ conceptually on the question whether animal boredom, like human existential ennui, should be conceived as connected to a lack of "meaning" in the animal's life. Wemelsfelder has proposed that it should be

so conceived, where "meaning" in the animal's life is then traced back to the animal's voluntary distribution of attention to novel activities and objects. Inhibition of this voluntary distribution is experienced as an unpleasant disruption of "attentional flow," leading to altered time perception (Wemelsfelder 2005, 83). By contrast, Burn 2017 has proposed the understanding of boredom as "an unpleasant emotion including suboptimal arousal levels and a thwarted motivation to experience almost anything different or more arousing than the behaviours and sensations currently possible" (Burn 2017, 141). This notion of boredom hence avoids alluding to "meaning in life" altogether.

Empirical Criteria of Animal Boredom

Due to the heavy reliance on subjects' self-assessment in the study of human boredom (e.g., questionnaires, interviews), it has been controversial whether there can be a scientific assessment of animal boredom at all (Wemelsfelder 2005, 1997; Young 2003, 153). This controversy is however increasingly calming down as outward behavioral criteria of human boredom become more widespread – criteria such as the behavior of pacing up and down, frequent yawning, or seeking novel sensations, as in the case of study subjects who reliably started to administer electric shocks to themselves when left alone in a quiet room (see Burn 2017, 146–148, for an overview). Such external behavioral criteria are then more easily applied to nonhuman animals.

Based on external behavioral criteria of boredom in humans, three groups of behavioral criteria of animal boredom are proposed by Burn (2017, 145f.):

- (a) Aversion to monotony: Bored animals should avoid monotonous situations or environments which they are conditioned to associate with monotony, and they should actively attempt to make monotonous environments more stimulating by seeking sensations, behaving restlessly, and consuming psychoactive drugs. Such sensation-seeking behavior can be severely harmful to the bored animal and other animals, as when they chew on or peck

at each other's limbs or ingest harmful substances or items.

- (b) Suboptimal arousal: Bored animals should show more awake inactivity and yawn more, and their hormone levels and brain activity should resemble that of bored humans (for details see Burn 2017, 148).
- (c) Altered time perception: Bored animals, if trained to expect a reward after a given time, should show anticipatory behavior earlier than animals in less monotonous environments; bored animals should also tend to treat intermediate time periods like longer time periods in a discrimination test; they should more often seek time indicators (such as sand timers or sliders); and they should show disrupted sleep patterns.

Furthermore, regarding all criteria from all groups, there should be a decrease in boredom behavior as soon as stimulation is increased (Burn 2017, 149).

Adaptive Value

Burn (2017) has further argued that boredom has adaptive evolutionary value for certain animals. Animals which are capable of learning are incentivized by boredom's unpleasantness to seek out more stimulating environments when they are faced with monotonous environments (Burn 2017, 143). The increase in learning then leads to an increase in the animal's fitness for survival. Since boredom motivates animals to seek more stimulating environments, it becomes chronic if animals are confined in monotonous environments. For this reason, chronic boredom is essentially a problem of captive animals (cf. Wemelsfelder 2005; Phillips 2009, 165).

Impact on Animal Welfare

Boredom affects welfare in three ways: First, it is an unpleasant affective state which immediately reduces the welfare of an animal. Although animal boredom has received comparatively little scientific attention, it is frequently mentioned as a factor impacting captive animal quality of life (McMillan 2005, 186), welfare (Rollin 2005, 3), and mental well-being (Seibert 2005, 285). This is

consistent with the fact that inevitable boredom is highly distressing for humans too (Burn 2017, 141). Secondly, boredom can lead to harmful sensation-seeking behaviors which in turn diminish welfare, including aggression toward other animals (ibid.) and ingesting or chewing on or pecking at inedible objects, including other animal's limbs (Burn 2017, 142). Third, since boredom leads to longer periods of awake inactivity and disrupted sleep patterns, boredom may also reduce the amount of activity contributing positively to animal welfare.

Prevalence and Responses

Just how prevalent chronic boredom is among animals confined by humans is currently impossible to determine due to lack of data. The hypothesis is however plausible that chronic boredom is among the leading causes of diminished welfare in captive animals, especially those used in animal agriculture. Some legislations, e.g., Swiss animal welfare law, recognize the problem of animal boredom by requiring producers to provide animals with distractions necessary for welfare (§2 Art. 6 Ziff. 1 TSchG). These are fleshed out in terms of substrate, e.g., straw for pigs. How successful these regulations are in reducing chronic boredom ought to be determined empirically.

Other means of environmental enrichment include social contact to conspecifics and other animals, visual or auditory representations of others, puzzles, manipulable objects, exercise devices, novel enclosures, novel furniture, toys, various stimuli including images, television, music, smells, novel nutrition, changing feeding schedules, novel treats, or opportunity to browse (Young 2003, 2 f.; McMillan 2005, 196). Discussions of enrichment however usually focus neither on agriculture nor on boredom but more often on the design of zoo enclosures.

Ethical Issues

Ethical Significance as a Harm

Animal boredom, like human boredom, is an unpleasant state. Especially its chronic form, it is detrimental to animal welfare and leads to further

harmful behaviors (see section “[Impact on Animal Welfare](#)” above). For this reason, boredom poses a harm to animals. In principle, therefore, boredom’s ethical significance should resemble that of other unpleasant and harmful states such as bodily pain, hunger, thirst, and anxiety. In contrast to these states, however, chronic boredom is not mentioned in influential animal welfare guidelines such as the Farm Animal Welfare Council’s “Five Freedoms.” This lack of recognition is due in large part to a lack of awareness of the problem but also due to a lack of solutions which are practicable within contemporary industrialized agriculture. The “tedium of confined lives” (Wemelsfelder 2005) is not easily evitable under the conditions of highly standardized, profitable animal agriculture. The recognition of animal boredom as a problem therefore adds to the argumentative stock of those opposed to industrialized animal agriculture.

The Ethics of Enrichment

Enrichment may help in the prevention of the harmful state of boredom. The implementation of measures of enrichment is therefore to be ethically preferred, other things being equal. However, the inherent monotony of modern animal agriculture makes it questionable whether enrichment is a promising approach all things considered. Environmental enrichment runs the risk of becoming an industry fig leaf if it is only used in a minimal fashion to prevent the most visible symptoms of boredom. A strategy of generous enrichment, where more novel space and distractions are provided to the animal than is necessary to prevent the most visible symptoms, is however likely unfeasible under the conditions of industrialized agriculture. The more thorough solution from the perspective of animal ethics is to avoid confining animals as far as possible, including a lowering of the number of animals bred into animal agriculture. There may however be cases outside industrialized animal agriculture in which it is either impossible or irresponsible not to confine animals, such as in sanctuaries for animals who require human care. In these cases, it is vital that the danger of boredom be recognized and prevented as far as possible using strategies of generous enrichment.

Conclusion

This article has presented key issues in the philosophy and science of animal boredom. Philosophers typically distinguish between “situative” and “existential” boredom. Only the latter form is likely to be exclusive to humans. The science of animal boredom is still in its fledgling stage, since methodological controversies have hindered its development until recently. An emphasis on external behavioral criteria, such as those proposed by Burn (2017), however makes it possible to investigate boredom’s prevalence and the effectivity of response strategies. From an ethical standpoint, animal boredom must be taken seriously both as a harmful state. Boredom’s prevalence in agriculture and the effectivity of prevention measures await empirical investigation.

Animal Welfare in the Context of Animal Production

David Fraser
Animal Welfare Program, University of British
Columbia, Vancouver, BC, Canada

[Animal care](#); [Animal ethics](#); [Animal husbandry](#);
[Quality of life](#)

Introduction

Traditionally, the term “animal welfare” has been used to refer broadly to the “quality of life” of animals especially when people raise concerns about how animals are treated. This entry attempts to clarify some of the confusion that has arisen around the term, partly because different people view the quality of life of animals through different value-based lenses.

Three Broad Concerns

In the 1700s and 1800s, concern about the treatment of animals was generally expressed in terms of “cruelty,” and the main focus was on deliberate acts of animal abuse or neglect. With the growing intensification of animal production since 1950, concern was often expressed about unintended effects of confinement production systems on the quality of life of animals, and these were generally captured under the broader term “animal welfare” (Woods 2012).

The term “animal welfare” has been used, especially in social commentary and debate, to capture three broad concerns that arise over the quality of life of animals (Fraser et al. 1997).

The first concern focuses on the “affective states” of animals including pain, fear, comfort, contentment, and other emotions and subjective states that animals experience as either pleasant or unpleasant rather than hedonically neutral. For example, commentators have called for animals to be treated in ways that prevent pain and distress or to be allowed to experience the pleasures of life.

The second concern focuses on the basic health and biological functioning of animals including appropriate nutrition, prevention of injury and disease, and appropriate protection from harsh weather and other dangers. Thus, the World Organisation for Animal Health (OIE) refers to “a critical relationship between animal health and animal welfare” (OIE 2012).

The third concern is that animals should be able to live in a reasonably “natural” way. This can involve two components. One is simply that animals should have natural elements in their environment such as sunshine and fresh air. A second concern is that animals should be able to live in ways that suit their natural adaptations including their natural behavior. Critics might call, for example, for animals to be able to carry out their natural feeding and nest-building behavior and to be fed on diets that suit their digestive systems.

Sometimes these different concerns go hand in hand. For instance, allowing a pig to wallow in mud on a hot day might be seen as good for the

pig's welfare because the pig will feel more comfortable (an affective state) and will have less disruption of bodily processes through heat stress (basic health) and because the animal can perform its natural cooling behavior (natural living).

However, the three concerns are sufficiently separate that the single-minded pursuit of any one often fails to address the others. A hygienic laboratory cage may provide a high level of physical health but allow animals little opportunity to perform their natural behavior. Generous feeding of dogs may provide the animals with pleasure but lead to health problems and a short life span. "Free-range" systems for pigs allow fresh air and natural behavior but often involve harsh weather and high rates of neonatal mortality.

The three areas of concern are emphasized to different degrees by different people. Many animal protectionists focus on the affective states of animals; they may call, for example, for pain management to be used for procedures such as dehorning and castration, whereas animal producers tend to downplay the significance of short-term pain. In general, animal producers who raise animals in indoor confinement systems tend to emphasize basic health to the extent that they justify keeping animals in very restrictive environments on the grounds that this helps prevent injuries and disease. In contrast, most studies show that members of the general public in Europe and North America tend to emphasize the naturalness of the environment and to downplay physical health (summarized by Sørensen and Fraser 2010); in fact, some people virtually equate animal welfare with "natural" living conditions. Ranchers who raise animals on pasture, together with some organic producers, tend to have a more mixed view, seeing natural, outdoor environments as generally providing a good life while acknowledging that the animals may suffer from some discomfort and ill health as a result.

Why Are There Such Different Views of Animal Welfare?

The different views of welfare have deep roots in Western culture which can be traced back at least

to the Industrial Revolution. At that time, opponents of industrialization tended to espouse values associated with agrarianism and the Romantic Movement. Such opponents valued nature ahead of technology and emotion ahead of rationality. They saw industrialization as reducing quality of life because it disfigured the natural landscape and forced people to give up wholesome rural living for dangerous factories and unhealthy cities. In contrast, promoters of industrialization, reflecting a set of values linked to the Enlightenment, saw nature as imperfect and looked to science and technology to overcome its shortcomings. They saw industrialization as a form of "progress" and interpreted the high productivity of the factories as evidence that the factory environments were well suited to the workers.

When animal production intensified during the twentieth century, the change was widely perceived in the industrialized countries as a further instance of industrialization, and it triggered a debate that mirrored the arguments that had arisen over the Industrial Revolution (Fraser 2008). Critics, often using explicitly industrial phrases such as "factory farming" and "animal machines," saw intensification as moving animals from wholesome natural settings into restrictive artificial ones which are not suited to the nature of the animals. They questioned whether animals could be healthy and happy in such environments and called for animals to be free to live in more natural ways. Promoters of intensification saw the new methods as using science and technology – vaccines, scientifically formulated diets, and insulated buildings – to protect animals from the hardships of nature, and they took the high productivity of these systems as evidence that they were well suited to the animals.

Critical Evaluation

Each of the three broad concerns has been the subject of debate and critical analysis.

With their focus on basic health, some animal producers and veterinarians have argued that because the productivity of animals is reduced by disease and injury, a high level of productivity

must demonstrate a high level of animal welfare. This view has been hotly contested since the 1960s. For one thing, high levels of physical health are seen as only one aspect of animal welfare. Moreover, intense genetic selection for very high levels of productivity has led to “diseases of production.” For example, genetic lines of dairy cattle that have been bred for very high milk production tend to have high levels of metabolic disorders and a short life span. Thus, although good health is almost universally acknowledged as fundamental to animal welfare, the links between health, productivity, and welfare are widely recognized as needing critical analysis.

Many people see the affective states of animals, or “subjective well-being,” as the ultimate criterion of animal welfare and regard good health, natural living conditions, and other factors as merely contributing to welfare inasmuch as they contribute to subjective well-being. Thus, the absence of pain and suffering and, conversely, the ability to experience pleasure and contentment are viewed as the definitive elements of animal welfare. In the environment in which a species evolved, such affective states are thought to have evolved to make the animal seek what is beneficial and avoid what is harmful to its evolutionary fitness (Dawkins 1998). In artificial environments, however, this correlation may break down. Animals (like human smokers) may not dislike, or even detect, pollutants that affect their health; animals may find rich diets highly palatable even though they lead to obesity and other health problems; vaccinations, although causing pain, can improve future health. To many people, therefore, animal welfare needs to be seen as a balance between subjective well-being and longer-term health.

The call for animals to live reasonably “natural” lives has been especially controversial. In Europe and North America, the tendency of the public to equate animal welfare with “natural” environments has led to calls for animals to be kept in outdoor systems. However, some animal producers note that outdoor systems present challenges including harsh weather and exposure to infectious diseases. Moreover, biologists who have studied the natural behavior of animals

point out that environments that appear natural to the human onlooker may not correspond well to the actual needs of the animals. For example, chickens are descended from jungle-dwelling ancestors, and they tend to avoid untreed pastures that are used in some free-range systems. Such considerations have led to more critical approach that calls for animals to be raised in ways that correspond to their natural adaptations. This would include physical and social environments that allow important types of natural behavior, temperatures that match their thermoregulatory capacity, and diets that correspond to their digestive systems.

If no single approach is likely to optimize animal welfare according to all criteria, the emerging practical response appears to be the development of two contrasting kinds of production systems. One accepts the health-protection features of controlled indoor environments but adds features that accommodate the natural adaptations, behavior, and preferences of the animals. For example, enriched indoor environments for laying hens can accommodate important types of natural behavior such as nesting, perching, and dust bathing while still preventing the entry of predators and disease organisms. A second approach begins with unconfined systems but adds greater protection from parasites, predators, and harsh weather. These different approaches are likely to appeal to different producers and consumers, but both should provide valid ways of improving animal welfare.

Animal Welfare as a Topic for Moral Philosophy and Science

As well as being a focus of public concern, animal welfare has also become a topic of study and debate among moral philosophers and scientists.

Early utilitarian philosophers, notably Jeremy Bentham and John Stuart Mill, although focused mainly on humans, tended to see good actions as those that promote happiness and prevent suffering. Following these ideas, some modern philosophers have emphasized the affective states of animals including states of pain and pleasure.

Others, adopting ethical views loosely linked with Aristotle, have called for animals to be able to live in ways that correspond to their “natures.” Yet others believe that animals should be able to develop their “capabilities” or express their “essential possibilities.” Thus, philosophers have adopted different ethical views, modeled largely on different theories of human quality of life (Appleby and Sandøe 2002) and corresponding roughly to the three broad concerns about animal welfare described above. In contrast, however, other philosophers, especially those who apply rights-based theories and call for all use and ownership of animals to cease, tend to dismiss animal welfare as an inadequate concept for decisions about human conduct toward animals.

Concern over animal welfare has also stimulated a large body of scientific research. In the early days of this work, some people believed that objective scientific measurements would resolve disagreements that arise because of the different views of animal welfare. In fact, however, the various scientists studying animal welfare tacitly adopted the different views of welfare as the basis for their research (Fraser 2008). Some sought to improve animal welfare by reducing problems of basic health, for example, by devising environments that do not cause injuries or that prevent the transmission of disease. Other scientists focused on affective states, for example, by developing methods to manage pain or methods of handling animals without causing fear (Hemsworth and Coleman 2011). Yet others tried to make rearing systems better suited to the animals’ adaptations, for example, by developing diets that match the animal’s digestive system or feeding systems that accommodate natural feeding behavior. As these examples illustrate, rather than arbitrating among the different views of animal welfare, the science incorporated the different views as a basis for a diverse program of animal welfare research and innovation.

At times, however, the different scientific approaches have led to conflicts because scientists using different criteria for animal welfare have arrived at different conclusions on contentious issues. For example, scientists who emphasize basic health may conclude that welfare is

satisfactory in very restrictive housing systems as long as basic health and productivity are assured, whereas scientists who emphasize natural behavior may conclude that welfare is poor in such systems simply because they are so restrictive. The key to understanding such disputes is to recognize that they result from the different scientists using different criteria of animal welfare (Fraser 2008).

Controversies

Beyond the issues noted above, other controversies have arisen over the welfare of farmed animals.

One controversy is simply over the semantic use of the term. “Welfare” has been used for centuries as a broad term referring to good fortune, health, happiness, and prosperity, and this usage has been the basis for using “animal welfare” in the sense of the animals’ quality of life. However, “welfare” also has a second, more recent meaning which refers to programs and reforms designed to provide food, shelter, and other benefits to vulnerable members of society. Given the possible confusion, the literature has generally followed (Broom 1991) in using “animal welfare” to refer to the state of the animal, not to external benefits provided. In addition, the historical meaning of “welfare” implied a positive state (*good* fortune, happiness, and so on). However, because much discussion of animal welfare is about negative states such as pain and deprivation, “welfare” (like “health”) has come to refer to a scale running from bad to good, not just the positive end of the scale.

A second controversy centers on whether animal welfare can be “measured.” It is certainly possible to measure many variables that are relevant to animal welfare such as disease incidence, the level of stress responses in different environments, and the strength of an animal’s motivation to carry out elements of its natural behavior. However, despite the best attempts to see animal welfare from the animals’ own “point of view” (Dawkins 1990), there is no purely objective way to balance the different elements of animal

welfare. There is no metric, for example, that allows us to say whether freedom of movement is more important or less important than freedom from ectoparasites. According to this logic, to speak of “measuring” animal welfare is to mistake the nature of the concept. By this view, the legitimate contributions of animal welfare science are to inform the debate about animal welfare and to improve animal welfare by identifying and accommodating the needs and natures of the animals, but not to “measure” animal welfare in some overall sense.

A third controversy is whether scientists and philosophers should use the term “welfare” in its everyday sense – as an umbrella concept covering the different concerns noted above – or in a more restrictive, technical sense. Some scientists, perhaps wishing to make animal welfare more amenable to objective scientific evaluation, have proposed technical definitions that link welfare to established scientific concepts such as fitness or to measurable variables such as longevity and productivity. Some philosophically informed commentators, attempting to identify the philosophical essence of the concept of welfare, have also proposed narrower definitions, often equating welfare with subjective well-being (Duncan 1996; Nordenfelt 2006). An alternative view holds that when a term is widely used in the public domain, there is a risk of confusion if scientists or philosophers use the term in a different or more narrow sense; indeed, scientific or academic discussion might thus become divorced from the public debate that they are intended to inform.

Summary

“Animal welfare” refers broadly to the quality of life of animals. In discussing animal welfare, people have expressed three broad areas of concern: the affective states of animals such as pain, fear, and contentment; the basic health and biological functioning of animals including freedom from disease and injury; and the ability of animals to live in reasonably “natural” ways. Because different people emphasize the different concerns to different degrees, they (in effect) espouse different

views of animal welfare which sometimes come into conflict. The different views of animal welfare have deep roots in Western culture, dating at least from the conflict spawned by the Industrial Revolution. The different views of animal welfare are also reflected in the different theories of animal ethics and in scientific research on animal welfare.

Introduction

The past half-century has witnessed a dramatic increase in both philosophical and social concern about animals. Much of this concern is about animals' moral standing and the ethical permissibility of various animal-harming practices. However, a parallel track of concern relates to animal mind and animal well-being. Some of the motivation for concern about animal mind and animal well-being can be traced to scientific curiosity; however, the investigation of what animals are like, and what makes an animal's life go well or poorly, is an important part of moral philosophy. Normative judgments about what humans owe animals usually presuppose some account of what is beneficial or harmful to them, and philosophical work in normative ethics therefore must proceed apace with conceptual and empirical work regarding animal welfare. In addition, an important historical and sociological aspect of

debates about animal welfare is that they take place in the context of a society in which animal use is pervasive. Often, the persons who investigate animal welfare, and the institutions in which such investigations take place, are closely connected to various forms of animal use, for example, agriculture and biomedical research. While investigations into animal welfare are often intended to improve the lives of animals being used for various human ends, such investigations are often permeated by political concerns as well. This entry reviews important philosophical and political issues relating to the definition and assessment of animal welfare.

Animal Welfare: A Science-Based Concept?

A major issue in the history and philosophy of animal welfare is the extent to which animal welfare is a scientific concept. A historically prominent view is that animal welfare or its assessment is "science-based," and this view continues to enjoy popularity in some quarters (see Tannenbaum 1995; AVMA 2003; Korte et al. 2007). Commentators who advance this claim usually seem to understand "science-based" as positively entailing empirical verifiability (or falsifiability) and as negatively being distinguished from "value-based" or "emotion-based" accounts of animal welfare. Other commentators who do not explicitly assert that welfare is science-based nonetheless define it in similar terms.

A close connection exists between science-based conceptions of welfare and the philosophy of logical positivism. Logical positivism, which dominated scientific thinking for a large part of the twentieth century, holds that only empirically verifiable or falsifiable statements are meaningful. Two corollaries to this view are that (1) statements about nonobservables, such as mind, are illicit unless translated into empirically verifiable terms and (2) evaluative statements, such as statements about aesthetics or morality, are meaningless because they are not empirically verifiable. Though logical positivism has since fallen from prominence in philosophical circles, it has played

a large part in the history of thought about animal mind and animal welfare. Rollin (1990) has shown how this philosophy influenced the development of psychological behaviorism, which held talk of animal mind to be illegitimate, and replaced such talk with talk of physiology and behavior. Hence, “animal welfare” as a concept referring to an animal’s subjective experience came to be replaced or defined by such terms as “stress” or “coping,” which, in turn, were then elaborated in behavioral or physiological terms that did not need to make reference to what an animal was thinking or feeling. In addition, positivism separated science from ethics, and so once talk of animal well-being was scientized, welfare as a concept was viewed as value-free (Rollin 1990).

Scientific information, such as information about an animal’s physiology or behavior, can be crucial in *assessing* what is beneficial or detrimental to an animal’s welfare. For example, scientific information can be helpful in determining whether an animal is experiencing pain, and pain is almost universally agreed to be relevant to an animal’s welfare. However, the view that animal welfare at the *conceptual level* is “science-based” is subject to numerous criticisms. First, logical positivism has been criticized for a number of reasons, for example, because the principle of verification it espouses cannot itself be verified (how does one empirically verify the claim that only empirically verifiable statements are meaningful? – This seems to be a value judgment), and because normal scientific practice involves both moral and methodological value judgments (Rollin 1990; Jones 1975). Furthermore, the moral theory of emotivism (a corollary to logical positivism), which holds that moral statements are nothing but emotive utterances with no truth-value, also appears untenable in at least the simple forms that preclude any degree of moral objectivity (Rachels 1993). To the extent that “science-based” views of animal welfare trace back to logical positivism and emotivism, they inherit these difficulties.

Second, in ordinary language the very meaning of the term “welfare” seems to refer to an individual’s well-being, to what is good or bad for that individual – this is by definition an evaluative

judgment (Fraser 1995). Thus, to assert that the concept of welfare is nonmoral and value-free seems to commit a category error. Third, it can be observed that no amount of scientific information in itself will answer questions about an animal’s welfare, because a person can always ask why such a thing is good or bad for the animal, and only an evaluative judgment can answer this question.

Competing Definitions of Animal Welfare

Once the moral nature of the concept of “welfare” is recognized, a second major issue in the definition of animal welfare concerns the specific definition of “welfare” that should be adopted. Multiple and at times competing definitions have been advanced, some with clear philosophical drawbacks. Fraser and colleagues (1997) organize definitions of animal welfare into three categories: “feelings-based” definitions, which focus on an animal’s mental states and how it feels; “natural-living” definitions, which focus on an animal’s ability to express natural (i.e., “species-typical”) behaviors or live in natural conditions; and “function-based” definitions, which focus on such things as normal physical functioning, the absence of disease, survival and reproductive fitness, and adequate coping (adaptation) to various environmental stimuli. Fraser has also proposed a related and partly overlapping taxonomy using “type 1,” “type 2,” and “type 3” definitions. Type 1 definitions of animal welfare define the concept in terms of single, directly measurable attributes, for example, an animal’s cortisol (stress hormone) levels. Type 2 definitions hold that animal welfare is a single attribute that cannot be measured directly, but which can be estimated indirectly using various measures. For example, one might argue that an animal’s welfare is a function of pleasure and pain and that while these mental states cannot be directly measured, behavior or physiological indicators can be used to estimate what an animal is feeling. Type 3 definitions hold that animal welfare is a function of multiple attributes that are not amenable to assessment in a determinate way, for example, a

function of physiological and behavioral measures, bodily integrity, natural living, and subjective feelings (Fraser 1995).

When considering the aforementioned definitional options, one fundamental philosophical question concerns the plausibility of definitions of animal welfare that do not make reference to an animal's subjective (i.e., conscious) experience, such as definitions based on evolutionary fitness, physiological parameters, or purely behavioral measures. As with science-based conceptions of welfare, nonmentalistic definitions of animal welfare may commit a category mistake: it seems to be the case that "welfare" *by definition* relates to mentalistic states such as desire, pleasure, or preference. Support for this view comes from the fact that it is difficult to articulate a positive account of why something advances or sets back an individual's welfare if that thing in no way relates to what the individual desires or prefers or what otherwise affects the individual's mental states. Said another way, definitions of "welfare" not referencing subjectivity in any fashion appear arbitrary.

The preceding argument can be strengthened by noting that the three major options in prudential value theory (i.e., philosophical theory articulating what it is that makes a life go well or poorly at the most fundamental level) all reference an individual's subjective experience in some fashion, though exactly how differs between theories. Hedonistic theories define value in terms of pleasure and disvalue in terms of pain. Desire-based theories define welfare in terms of the satisfaction of desires, and of course an individual must be conscious in order to have desires. Furthermore, desire satisfaction may be valuable because satisfied desires tend to bring pleasure (returning us to hedonism) or because they correlate to some other kind of mental state such as cognitive appreciation. Objective value theories hold that a good life is characterized by certain objective goods (e.g., friendship, education or, in the case of animals, perhaps natural behaviors). This may be true even if an individual does not desire these goods. Even so, the way in which these goods putatively contribute to an individual's welfare still likely references what that individual experiences. For example, it might be held that education is a good, even for persons who

do not desire to be educated. However, when we consider the value of education for such persons, its value will be explained in terms of how it affects their understanding and experience of themselves and the world around them. Furthermore, the most plausible version of such objective theories may require that an individual desires the objective goods in question (see DeGrazia 1996; Heathwood 2006 for further discussion). (To be clear, an "objective" prudential value theory should not be confused with a "science-based" account of welfare. Moral value judgments can putatively be objective as well.) For present purposes, we need not choose between these different categories of prudential value theories (or choose a particular variant within a category), since the point at issue is simply that a plausible theory of welfare should reference the subjective experience of the individual whose welfare is in question.

As noted above, behavioral, physiological, and functional criteria may still be relevant to animal welfare not as definitional criteria but as criteria of assessment. For example, it could be argued that it is important for animals to fulfill natural behaviors because these behaviors correspond to preferences or needs, which when thwarted prevent an animal from experiencing satisfaction and/or cause unpleasant mental states such as fear, anxiety, or suffering. Similarly, one may hold that the absence of disease is important because disease causes pain or suffering, shortens an animal's life and thus its future opportunities for satisfaction, or reduces an animal's present opportunity range because of impaired eating, grooming, mobility, playing, etc. In addition, physiologic criteria such as cortisol (stress hormone) levels may be indicators of welfare: when an animal is experiencing unpleasant mental states, one might try to indirectly substantiate this by looking at cortisol levels (though, as discussed below, this approach can be problematic). But it is important to emphasize that these physiologic and behavioral indicators are being used to assess the welfare of an animal and not to define its welfare.

It might be objected that bodily integrity or good biological functioning (e.g., the absence of disease) is at least partly definitive of an animal's welfare – that is, intrinsically important – and not

just of instrumental importance as it relates to subjective experience. This kind of argument comes into play, for example, in discussions about bodily modification, such as the tail docking of a dog or cow. In such a case, some persons might harbor the considered judgment that the tail docking harms the animal even if the surgical procedure were (let us assume for the sake of argument) painless and did not otherwise affect the animal's mental states in any way (such as through altered socialization). Plausible as this intuition might seem, it is unclear whether it can be defended at the principled level, as it seems to encounter the same difficulties as any definition of welfare not referencing subjectivity. Ultimately, whether bodily integrity or some kinds of biological functioning have intrinsic value might come down to a considered judgment that a person either accepts or rejects. However, even if the intrinsic importance of bodily integrity to animal welfare is accepted, the likely upshot is that an animal's subjective experience becomes a necessary but not sufficient component of any plausible definition of welfare – *not* that subjective experience becomes irrelevant. In most cases, welfare-relevant states still seem to map onto subjective experiences, with such considerations as bodily integrity being exceptional.

The requirement that a plausible definition of animal welfare must reference subjectivity seems to rule out the “type-1” definition introduced above, since mental states are not directly measurable. This requirement also rules out “natural living” and “function-based” definitions, since neither of these definitional categories directly reference an animal's subjectivity. However, both “natural living” and “function” might still be highly relevant to an animal's welfare at the level of what *impacts* or *affects* its welfare and thus might be relevant to the *assessment* of animal welfare. Even so, the subjectivity requirement still leaves open most major options in prudential value theory, as well as the question of whether welfare should be regarded as a “type 2” or “type 3” concept. When considering these options, problematic cases are easy enough to identify. Something that brings an animal pleasure in the short term (say, eating a certain food) may detract

from its welfare later on, for example, by causing disease. Similarly, an animal may go to great lengths to satisfy a desire, such as the desire to reproduce, and in so doing impose other welfare costs on itself, such as pain or injury. If animal welfare is to be regarded as a type 2 concept, then it would seem that a clear winner in prudential value theory must be identified – welfare must be cashed out in terms of pain/pleasure, desire, or objective goods, but not some combination thereof (such a combination would correspond to a type 3 definition). Picking a winner might be possible, despite problematic cases: for example, the fact that an experience brings pleasure now but pain later need not be regarded as an objection to simple hedonism, since something that is good in the short term can also be regarded without contradiction as bad “all things considered” (Heathwood 2006). Just the same, one may attempt to “correct” desires by stipulating that they be informed or that what is of value is what one “desires to desire” (Smith et al. 1989; DeGrazia 1996; Heathwood 2006). However, the situation gets more complicated from here. Simple hedonism is vulnerable to other objections that cannot be reviewed here, and these objections may or may not be successfully answered by more sophisticated versions of the theory. Similarly, informed desire theory may just collapse into an objective value theory, but objective value theories have their own liabilities (see DeGrazia 1996 for further discussion).

At present, there remain unresolved issues in the conceptualization of animal welfare, and it may be the case that the most defensible welfare definitions are pluralistic and indeterminate (i.e., type 3). However, it should be noted that many political disagreements about animal welfare do not trace back to these philosophical difficulties but rather to obviously problematic definitions of the concept (e.g., purely physicalistic definitions) or to questionable cost-benefit calculations (see below).

The Harm of Death

An important issue in the assessment of animal welfare is whether death *per se* harms sentient

(conscious) animals. While death might harm animals in virtue of the pain or distress that it causes, some philosophers have historically argued that *painless* death does not harm animals. The usual reason given for this is that animals are non-linguistic and non-self-conscious beings and as such they are unable to form an abstract preference to remain alive, since they do not understand the concept of “death.” Lacking this preference, then, killing them painlessly does not violate this preference. Further, some philosophers have gone so far as to argue that in order to have any morally relevant interests *whatsoever*, a being must be able to use language, since to have an interest is to prefer that a certain state of affairs obtain in the world, and one cannot make this judgment without understanding language (see, e.g., Frey 1980).

Views about whether or not death harms animals have serious implications for many of our animal-using practices. Many forms of animal use, notably including agriculture and scientific research, result in animal death and often by necessity (it is, for example, impossible to obtain meat without killing an animal). While these activities might be reformed so as to better attend to animals’ welfare while they are alive, if killing animals generally harms them, then it will be difficult or even impossible to continue these forms of animal use without harming animals in some way.

Despite a few historical arguments to the contrary, the trend in recent philosophical work on animal ethics seems to be that most commentators argue that death *per se* does ordinarily harm sentient animals. Harman (2011) helpfully reviews several arguments advanced in the literature for why death does not harm animals and concludes that each is false; the three most important are reviewed here.

First, it could be argued that death for a person is only bad because it frustrates her desires and plans for the future, and since nonhuman animals do not have abstract desires and plans for the future, death does not harm them. Putting aside the empirical question of whether or not animals have abstract desires and plans for the future, this argument is false, as Harman retorts, because it is

not true that death only harms an individual if it frustrates her desires and plans for the future. Death, even painless death, could also harm conscious (but non-self-conscious) individuals because it deprives them of future opportunities for pleasure or preference satisfaction. This argument can explain why, for example, death would be a harm to an infant or a mentally disabled person who enjoys life but is not capable of forming future-oriented preferences or projects. Similarly, it can explain why death ordinarily harms conscious animals (Harman 2011; see also DeGrazia 1996).

However, a second argument holds that while death prevents animals from future enjoyments, this is best viewed as the deprivation of a benefit and not as a harm. The significance of this distinction between harm and foregone benefit would appear to lie in the weight given in moral philosophy to the distinction between positive and negative obligations – philosophers often seem to be in greater agreement about our obligations not to harm others (negative obligations) than they are about our obligations to benefit others (positive obligations). If killing an animal does not harm it but merely deprives it of some benefit, then it might be thought that our obligation not to kill animals is thereby weaker or even absent. Harman (2011) argues that this view may be rebutted by noting that some actions that deprive an individual of benefit do actually seem to count as harms. For example, if someone deafens you, you have been deprived of the benefit of hearing but you are also harmed by this. Though Harman does not explain why being deafened is a harm, one can make sense of this judgment by noting that to harm an individual means to set back their interests or make them worse off, and as regards the infliction of both deafness and death, an individual is being made worse off relative to how they would have been had one not acted.

Third, one may hold that humans have certain “time-relative interests” that arise based on our psychological continuity with our future selves, such as an interest in completing a college degree or writing a book. These are interests that take a long time to satisfy and, at any given time, the completion of which often lies well into the future,

long-term life projects being a paradigm example. Since nonhuman animals have a lesser degree of psychological continuity with their future selves than do humans, nonhuman animals have either very weak or no time-relative interests. In a sense, the lesser degree of psychological continuity that nonhuman animals have with their future selves effectively “discounts” the strength of their interests as such interests are moved further into the future (think of a percentage multiplier gradually moving from “100%” to “0%” as one moves further into the future). Therefore, the time-relative interest account (TRIA) may allow that death harms animals, but it would also hold that death normally harms humans to a much greater degree (see DeGrazia 2007).

Importantly, even if animals do not have time-relative interests, one may hold that death significantly harms them on account of depriving them of future goods that are not time-relative in nature. However, Harman interprets the TRIA view to imply that killing an animal does not significantly harm the animal. Accepting this premise, she then argues this view must be false because it cannot explain certain considered judgments about animals that have moderate psychological continuity (say, a few years into the future). Consider, for example, a horse with a serious illness that will live a healthy life for 5 years, but then will suffer significantly for several months and die. If treated now with surgery, the horse will only suffer for 2 weeks – and not nearly as severely as it otherwise would 5 years from now – during the post-operation recovery. Furthermore, if the surgery is done now, the horse will live a healthy life for another 15 years. Intuitively, many persons would say that the best decision for the horse’s welfare is for it to have the surgery. However, Harman argues that TRIA cannot explain why this decision is permissible, since the horse’s short-term loss (pain from surgery) cannot, on this view, be balanced against an interest that it has far into the future. But because the intuition about surgery being the right decision seems sound, Harman argues that the TRIA view cannot adequately support the judgment that death ordinarily harms animals much less than it harms humans, and certainly

TRIA cannot support the judgment that death does not harm animals at all (Harman 2011).

Finally, the view that animals are not harmed by death suffers from two more general difficulties. First, it might presume that only abstract preferences are of prudential value. Not only does this leave out nonlinguistically based preferences (which some philosophers have argued animals do possess), but in addition it also omits both objective goods and other mental states (e.g., pleasure and pain) as relevant to an animal’s welfare. Second, if these other things (e.g., foregone pleasure) are acknowledged to be relevant to an animal’s welfare, then the argument that animals are not harmed by death seems question-begging: just because animals are not harmed in one way (by thwarting an abstract, linguistically based preference), it should not be concluded that they are not harmed at all. If harming an individual is generally understood as making the individual “worse-off,” and if animals are plausibly thought to be worse-off in virtue of being deprived of valuable future experiences, then it is hard to see why we should not conclude that sentient animals are normally harmed by death.

In having this discussion, it should be kept in mind that in some specific cases, death might not harm sentient animals. Specifically, this will be true when the animal’s future life would not be of value to it, for example, because the animal is experiencing intractable suffering. Furthermore, it should be kept in mind that some animals experience intractable suffering at human hands. For animals in these circumstances, death might be preferable to continued life, but it seems erroneous to conclude that the animals are not harmed at all. Were it not for the first harm inflicted upon them (which results in their intractable suffering), death would not be considered a release from suffering and thus nonharmful. In the greater context, then, such animals are still harmed by death since they are worse off as compared to a state in which they were not harmed in the first place.

Hence, while a number of arguments may be advanced to show why death does not ordinarily harm animals (i.e., set back their welfare), all of these arguments are problematic at the least and untenable at most.

Philosophical Considerations in the Assessment and Interpretation of Animal Welfare

Apart from the question of whether death harms animals, philosophical considerations also enter into the scientific assessment of animal welfare in other respects. Primary among these philosophical considerations is the question of whether scientific “assessment” is needed in the first place to make informed judgments about what affects an animal’s welfare. By “scientific assessment,” it is meant an attempt to directly answer a question about animal welfare using empirical data obtained from a scientific study specifically examining this question. An example of scientific assessment of animal welfare would be to design a prospective, controlled, and randomized study looking at various welfare-related behavioral and physiologic outcomes in pigs housed in one of two different agricultural housing systems. Should one be agnostic about what affects an animal’s welfare, or assume that a particular kind of treatment does not adversely affect an animal’s welfare, until scientific studies specifically affirm that it does? For example, should it be assumed that gestation crates, which severely restrict sows’ (pregnant pigs) mobility, do not adversely impact sows’ welfare until there is strong, direct scientific support for this judgment? Or might defensible judgments about animal welfare be based on other considerations as well?

In debates about the animal welfare implications of agriculture, biomedical research, and other animal use activities, it is not uncommon for certain stakeholders to claim that judgments about animal welfare should be based on “sound science.” At least one way of interpreting this claim is that we should only come to conclusions about animal welfare when those conclusions are based on scientific studies directly examining the welfare claim in question. At first glance, it might seem eminently plausible to maintain that defensible judgments about animal welfare require well-designed scientific studies to back them up. However, this position assumes that we cannot reasonably conclude in this example that gestation crates harm sows on the basis of considerations

other than evidence from direct scientific studies. Specifically, this position excludes such alternative forms of evidence as sows’ normal behavior in nonconfinement settings, evolutionary considerations, our perceptions of sows’ mental lives (as informed by both everyday experience and perhaps other kinds of scientific studies), and our own judgments about how strict confinement would affect our welfare. Note that some of these alternative considerations are “scientific” in nature, but they constitute an indirect form of evidence rather than the direct form of evidence putatively offered by scientific studies examining gestation crates specifically. Furthermore, even where data are direct – that is, obtained specifically from sows housed in crates – questions might arise about their adequacy: do direct but anecdotal observations of sows’ behavior in gestation crates count as admissible evidence, or is the only acceptable evidence that provided by well-controlled studies with larger sample sizes?

On the one hand, we wish to avoid *inappropriate* anthropomorphism and judgments about welfare that cannot be supported by good reasons. We might worry that in the absence of scientific information to support a particular judgment about animal welfare, we might inappropriately project views about our own welfare onto animals or otherwise make an error in assessment. On the other hand, appeals to the necessity of scientific justification, or claims about when anthropomorphism is inappropriate, may beg the question as to what constitutes a good reason. Anthropomorphism – the attribution of certain human qualities, desires, preferences, or mental states onto animals – is not by definition inappropriate; it is only inappropriate if the animals do not share the similarities to humans in question. Based on general considerations of anatomy, physiology, behavior, and evolutionary theory, we might claim to have good reason to think that certain actions harm animals, even in the absence of well-designed scientific studies investigating specific hypotheses about the animal welfare effects of certain practices (see DeGrazia 1996). For example, it might be argued that gestation crates are detrimental to sows’ welfare on the basis of prior warranted beliefs that sows are conscious, that

they tend to move around and perform various behaviors when allowed to do so, that these behaviors correspond to preferences or pleasurable experiences, and that by analogy it would be considered detrimental to human welfare to be so severely confined. Thus, the view that judgments about animal welfare must always be supported by specific scientific studies is open to criticism in some cases.

If it is accepted that some direct scientific assessment of animal welfare is needed, questions then arise about what constitutes appropriate evidence and experimental design. For example, what degree of weight should be assigned to anecdotal observations, such as the observation that when initially placed in crates or tethered, sows try vigorously to escape (HSUS 2009)? Isolated anecdotal observations may be discounted because they represent statistical outliers or are made in uncontrolled conditions, but such observations do nonetheless represent a form of evidence. Furthermore, scientists' aversion to anecdotal evidence has been criticized as perhaps arising from a positivistic ideological bias (Rollin 1990). A related issue is whether an animal's cognition and preferences should be assessed in controlled laboratory conditions or more naturalistic conditions. Laboratory assessment allows for the control of experimental bias and confounding variables but may introduce artifactual elements that change an animal's behavior. Welfare assessment under naturalistic conditions avoids such artifactual elements, but under naturalistic conditions it may be more difficult to control for bias and confounding (though increasing the number of observations can help to compensate for statistical outliers) (DeGrazia 1996).

Methodological value judgments – defined here as judgments involved in scientific practice that are underdetermined by data, underdetermined by inference rules or criteria, or otherwise concerned with what makes for “good” science or knowledge – also enter into more specific elements in the design of scientific experiments assessing animal welfare. One such judgment concerns the choice of alternative conditions whose welfare impacts are being compared. Some philosophers have considered the

concept of animal welfare on its own terms; however, much animal welfare science takes place within the context of agricultural production systems or biomedical research, where welfare assessments (e.g., housing system comparisons) are often performed with pragmatic or economic considerations in mind.

For example, the American Veterinary Medical Association (AVMA) published a review of housing systems for pregnant sows (AVMA 2005). Not only did the AVMA explicitly acknowledge the relevance of economic considerations in assessing the welfare impact of various housing systems, but in addition the only housing systems that were compared were systems compatible with industrial farm animal production, including gestation crates, indoor group pens, and tether stalls. The comparison thus excluded sows in completely free-living conditions, as well as alternative housing systems such as hoop barns or pasture-based hut systems. Though the AVMA did not explicitly address the criteria guiding their selection of alternative housing systems, economic considerations likely played a part, since the excluded housing systems are likely incompatible with current industrialized production systems. Hence, the AVMA's conclusion that none of the three housing systems examined is clearly preferable to another (AVMA 2005) must be viewed with this limited selection of alternatives in mind.

Similar issues attend to the assessment of animals' preferences among a range of alternatives. Haynes (2011) observes that “unless the range of preferences is large, we cannot be sure that an animal is simply choosing the lesser of evils. We cannot also be sure that an animal can distinguish between what the present situation has to offer and what the longer term consequences of that choice might be.” Experimental design also involves methodological value judgments that affect our interpretation of whether an animal has a preference between alternatives at all. For example, one experiment offered sows 1 kg of straw if they performed a particular operant response. Since the animals rarely performed the behavior necessary to obtain the straw, even prior to farrowing when sows normally build nests, the author of the

study concluded that sows have little motivation to use straw. However, a follow-up experiment allowing sows to perform an operant response to gain access to a pen furnished with 18 kg of straw showed that the animals had a strong motivation to gain access to the pen. The author of this study concluded that 1 kg of straw was too little to be significant to the animals (see Fraser 1995). Decisions regarding other experimental variables might also affect our interpretation of the results of scientific studies assessing animal welfare. These variables might include, but not be limited to, the type, timing, and duration of an aversive stimulus; the time course of the response being measured; and choice of species of sex (Mason and Mendle 1993). To the extent that these and other choices are features of experimental design that precede data collection, they involve scientists' judgment and thus can be viewed (for the purposes of this discussion) as epistemic value judgments.

Yet another type of methodological value judgment concerns the correlation of measurable attributes, such as physiological variables, with mental states. For example, an animal's cortisol levels may be taken as a measurable proxy for nonmeasurable mental states, such as anxiety. In order to say with certainty that a particular measure correlates with a particular mental state, one would need an independent way to verify the existence of the mental state in question. However, since mental states are private, they can never be verified independently of the measures that are correlated with them. The basis for the correlation between measure and mental state is thus inferential, where mental state attributions are based on other evidentiary considerations than the one in question (e.g., other behavioral or physiological measures, evolutionary considerations, analogical reasoning to what correlations can be made in the case of humans, and so on). Methodological value judgments must also be made in many cases where different sources of evidence conflict as to what they suggest regarding an animal's welfare. For example, behavioral measures may indicate that an animal finds a particular situation unpleasant, while physiological measures may not directly support this inference (Mason and Mendl 1993).

Finally, methodological value judgments must be made when determining that sufficient evidence has accumulated to support a particular conclusion about the effects of something on an animal's welfare. For any given scientific investigation, normal science operates with a more-or-less standard set of statistical conventions (e.g., a 0.05 type I error threshold in classical significance testing) for arbitrating between "true" and "false" claims; however, it is important to acknowledge that these conventions represent value judgments about the sufficiency of evidence and are not indisputable. In fact, the level of evidence that is sufficient or appropriate in a given situation will depend on such things as the goal of the activity in question (e.g., harm avoidance versus knowledge accumulation for its own sake) and what is at stake if a wrong inference is made (Rudner 1998). For example, many philosophers writing about risk analysis have argued that more relaxed type I error thresholds should be adopted, since the purpose of risk analysis is to inform policy choices about the avoidance of possible harm and since standard scientific statistical conventions would unduly defer policy choices about such things (see, e.g., Shrader-Frechette 1991). A similar argument might be applied to policy decisions about animal welfare. In addition, since different studies investigating the same question may yield contradictory results, methodological value judgments must be made in deciding which study to prioritize and when different studies, taken together, provide sufficient evidence to form a conclusion.

It is important to be clear about the practical upshots of recognizing methodological value judgments in the assessment of animal welfare. Of course one such upshot is that empirical data alone are insufficient to decide the issue when assessing animal welfare and that additional assumptions and inferences must be made. This in itself is not troubling from a philosophical standpoint, though it does further undermine the notion that the assessment of animal welfare can be conducted in a value-free way. What is more important to recognize is that in some cases, methodological value judgments may be contestable or even indefensible. For example, while elevations

in cortisol levels may sometimes be plausibly associated with aversive mental states, such elevations may also be associated with novel and even pleasurable conditions. In addition, cortisol levels may sometimes be normal in conditions that are detrimental to animal welfare as evinced by other criteria (Fraser 1995). Whether a particular methodological value judgment can be defended is a determination that will most likely have to be made on a case by case basis, for example, by considering other sources of evidence in addition to the one in question, as well as more conceptual considerations relating to what one should expect a particular evidential source to tell us in a given situation. In some cases, available data may underdetermine the correct inference. However, it need not be assumed that this will be the case. For example, Mason and Mendl (1993) argue that discrepancies between different sources of evidence can often be resolved by a more careful consideration of the evolutionary function of particular responses.

Value Judgments in the Weighing of Interests

Many animal welfare assessments take place within the context of comparing different laboratory or production environments (e.g., different housing systems, different methods of euthanasia). In such circumstances, there may be both advantages and drawbacks of each alternative being compared, thus necessitating harm-benefit (or risk-potential benefit) assessments. Such harm-benefit assessments are value-laden, and even where there is agreement about what interests animals have, there may be disagreement about the degree to which interests are advanced or set back by specific actions or conditions, and the overall harm-benefit analysis for a particular practice or environment. Again consider farm animal housing systems as an example. Some persons may emphasize the benefits of controlling feed and temperature, preventing attacks from other animals, and lowering the risks of some infectious diseases as speaking in favor of indoor, intensive confinement of farm animals. Other

persons may argue that infectious disease risks of outdoor confinement are small; that animal feeding, temperature, and physical protection can be adequately accounted for by nonintensive conditions; and that living freely and in accordance with the animal's nature outweighs any putative benefits of intensive confinement (e.g., see, Fraser et al. 1997, Table 1; McGlone 2006 for discussion).

Another example of value judgments affecting the weighting of animals' interests comes from Larry Carbone (2004). Citing the debate over laboratory guinea pig cage size in the late 1980s, he explains that this was the first time the United States Department of Agriculture (USDA) had used a scientific study to justify changes in minimum required cage size – a reduction by almost one-half. The study cited by the USDA as evidence for making this change concluded that guinea pigs spend “75–88% of their time in about 47% of their cage, mostly along the wall” (Carbone 2004, p. 112), while 25% is spent in other parts of the cage. The authors of the study concluded that the pigs' predilection for wall-hugging justified a reduction in cage size, since additional space was going relatively unused. However, as Carbone explains, interpreted another way 25% of the time is 6 h a day, which is surely a considerable amount of time. Furthermore, even if space went unused by the pigs, it might have been used for bowls or other objects, which would further decrease available space for the animals when placed in a smaller cage. Clearly a value judgment is involved in interpreting these results.

As compared to judgments about moral obligation and right conduct, judgments about the prudential significance of animal interests, or harm-benefit assessments, may be less amenable to determination by specific principles; there seems to be a heavy intuitive component to such judgments. But this does not mean that all such judgments should be regarded as equally plausible. For example, it seems implausible to the authors to say that the benefit of avoiding a small risk of infectious disease outweighs the harm of intensive confinement for intelligent and social animals. It is also important to reiterate that

harm-benefit comparisons are conditioned by the selection of alternatives being compared, whether these alternatives are broadly different or just variations on a theme. For example, any number of variables within a given sow housing system may be subtly changed, and this may affect the overall harm-benefit calculus for that system. Another important consideration in the weighing of harm and benefit is bias. One way to assess whether different judgments about animal welfare (even when highly intuitionistic) are equally plausible is to ask whether any factors are present that might distort the evaluations of a given person, as discussed in the next section.

Moral Bias in Welfare Definition and Assessment

As discussed in the prior sections, the scientific study of animal welfare is permeated by a number of methodological and moral value judgments, including judgments about how data are interpreted, how experiments are designed, what alternatives are being compared, and others. This raises the possibility that moral bias could inappropriately influence how such judgments are made and thus the conclusions reached by scientists studying animal welfare. Because methodological value judgments are ineliminable from animal welfare science, ensuring the integrity of this science is not simply a matter of “making sure” that the science is insulated from evaluative considerations or otherwise kept “purely objective.” Rather, close attention must be paid to subtle considerations of experimental context, framing, design, conduct, and interpretation.

A number of scholars have raised concerns that animal welfare science is permeated (to varying degrees) by bias (e.g., Carbone 2004; Haynes 2008, 2011; Rollin 1990; Weaver and Morris 2004). One bias that has already been discussed is a positivistic bias (see Rollin 1990). A second kind of bias is moral bias, specifically a bias associated with a moral commitment in favor of some kinds of animal use. Such a bias might result in scientific studies being subtly or not-so-subtly designed, conducted, or interpreted so as to favor

conclusions congenial to the interests of animal users. Furthermore, since animal welfare scientists also sometimes participate in ethical debates about animal use (see Fraser 1999), moral bias in this field might result in the preferential adoption of definitions of animal welfare or normative ethical views that are supportive of animal use at the conceptual level.

One source of concern about moral bias relates to the field’s history. Haynes (2008, 2011) observes that the discipline of animal welfare science initially developed in institutions and organizations closely linked with animal agriculture and animal research, rather than institutions with no vested interest in these activities. Such institutional relationships seem to persist, insofar as contemporary scientists studying animal welfare are often appointed in agricultural colleges, medical schools, or schools of veterinary medicine. Not only does animal use occur in all of these environments, but in addition the political culture of these environments tends to be aligned closely with the culture and values of commercial agriculture and/or biomedical research. Similarly, research into animal welfare science is sometimes carried out by scientists in the employ of animal-use industries. For example, the aforementioned study relating to guinea pig cage size was authored by scientists from Charles River Laboratories, a prominent laboratory animal breeder (Carbone 2004).

By themselves, such institutional relationships might indicate a moral conflict-of-interest, but they do not show that bias actually permeates research in animal welfare science; conflicts-of-interest might sometimes be successfully managed. However, an examination of some scientific research and opinion produced by the animal welfare science community (or closely aligned groups, such as veterinarians) does substantiate concern about bias.

One line of evidence concerns the way in which “animal welfare” is defined. Haynes (2008, 2011) argues that the way in which persons in the scientific community define animal welfare “seems to play a major role in supporting merely limited reform in the use of animals and seems to support the assumption that there are conditions

under which animals may be raised and slaughtered for food that are ethically acceptable” (Haynes 2011, p. 105). One reason for this is that persons in the animal welfare science community have tended not to define death as a harm. In so doing, the concept of “humane care and use” came to be defined in such a way that activities involving the death of animals, such as agriculture and biomedical research, could (at least in theory) be conducted in such a way that they did not harm animals. Persons who wish to justify these activities need not rely on this assumption, but the assumption makes the activities seem less morally problematic and perhaps not even morally problematic in the first place, thus circumventing the need for positive justification. The philosophical question of whether death harms animals has already been discussed. Here, it should be noted that from a historical standpoint, the presumption of the welfare science community that death does *not* harm animals does not seem to have been driven by explicit philosophical argument, as much as (it would seem) by a culture of animal use that would find the conclusion congenial.

As already discussed, animal welfare is sometimes defined purely in terms of physiologic measures or “coping.” Not only is this problematic at a conceptual level but it also raises concerns about moral bias. For example, Weaver and Morris (2004) examined a review of sow gestation crates conducted by the *Australian Journal of Agricultural Research*, where the authors of this review concluded that there is no convincing scientific evidence that sow gestation crates are detrimental to the animals’ welfare. Weaver and Morris (2004) controvert this judgment, arguing that “when all available scientific evidence is taken into account, there are convincing arguments for a total ban on the extreme degree of confinement provided by sow stalls.” One reason for these discrepant conclusions is that the authors of the original review used a definition of animal welfare based narrowly on “coping” and elaborated principally in terms of physiologic measures. The result of this is that important lines of evidence substantiating the negative welfare effects of gestation crates were ignored (Weaver and Morris 2004). While Weaver and Morris (2004) do not

specifically opine on why these issues arose in the review, it seems reasonable to speculate that pro-industry bias might have been at play, insofar as sow gestation crates are widely used by the pork industry and are vigorously defended on economic grounds (Weaver and Morris 2004). This kind of issue seems to have arisen in some other studies of gestation crates as well (see McGlone 2006; AVMA 2005). Given the larger institutional and economic context, it seems unlikely that the adoption in multiple instances of a definition of “welfare” conducive to the defense of gestation crates is purely coincidental.

Moral bias may also intrude into the definition of animal welfare when human concerns are built into the definition. For example, the ease of managing large numbers of animals and economic productivity are often built into the “welfare” assessment of different sow housing systems (see McGlone 2006; AVMA 2005). As Mench (1998) explains, “[f]arm-animal welfare science is bounded not only by ethics but by complex economic and social constraints, including profitability, worker health and safety, food cost and safety, policy considerations, consumer acceptance, and environmental sustainability.” Whether or not these considerations properly belong in an ethical analysis of confinement agriculture, they certainly do not belong in an assessment of the *welfare* impact of various housing systems on the animals. Economic and pragmatic factors might or might not be sufficient justification for harms to animals, but we should not let them obfuscate our assessment of when harm is occurring.

A second possible line of evidence for the intrusion of moral bias into animal welfare science concerns the manner in which harm-benefit assessments are made. As already discussed, such judgments are heavily intuitive. Despite this limitation, it seems implausible to suggest, as some commentators have, that the intensive confinement of farm animals is actually better for the animals than alternative housing systems. The welfare cost of confining intelligent and social animals in barren environments prohibiting almost all movement (and also causing some physical problems) seems so great as to vastly outweigh a reduction in other risks (e.g.,

aggression from other animals). Differences in evaluative judgments about harm-benefit tradeoffs do not of necessity indicate bias. However, it is notable that according to poll data and published opinion, most members of the general public, most ethicists, and a good many animal welfare scientists now believe that intensive confinement of farm animals is highly detrimental to their welfare; for many persons, the question seems beyond any reasonable dispute. In practice, the only persons who seem to defend such intensive confinement systems on welfare grounds are representatives of industry and certain members of the animal welfare science community. Given the institutional factors discussed above, this suggests a possible pro-industry bias amongst some members of this scientific community.

Contestable harm-benefit calculations can be facilitated by conducting housing comparisons that only include “bad” options. As discussed above, not only do such comparisons involve value judgments, but to the extent that they make certain animal-use practices seem less harmful or problematic, they too raise concerns about bias. On this point we draw attention again to the AVMA’s (2005) comparison of housing systems for pregnant sows.

In a related vein, the concept of “net” or “cumulative” welfare also raises concerns about bias. Here, the idea is that as long as the “balance” of welfare is positive, then welfare is considered good, and a housing system or procedure may be considered unproblematic (McGlone 2006; Mench 1998). This approach essentially allows for some harms to animals to be legitimated without ethical argument, since if they are outweighed by enough positive elements, then welfare is good and the practice does not appear to even require ethical justification.

A final way that moral bias might intrude into the work of animal welfare scientists relates to their normative appraisal of animal use practices, such as raising animals for food or using them in biomedical research. Here it is helpful to recall that most persons (and not just animal welfare scientists) might have a moral bias when it comes to these issues, insofar as the moral defensibility of animal use is widely assumed in most cultures and many people directly benefit from

such use. Any institutional ties between animal welfare scientists and animal users would only potentiate this preexisting issue. As possible empirical evidence of such a bias, consider a 1999 article on the relationship between the philosophical discipline of animal ethics and the discipline of animal welfare science. The author of this article has the laudable goal of increasing dialogue between the two communities but attributes much of the historical lack of dialogue to the fact that prominent animal ethicists have adopted normative ethical theories incompatible with animal use (Fraser 1999). This is a curious observation, since the scientific investigation of whether certain ways of treating animals are beneficial or detrimental to their welfare should not logically depend on whether various animal-use practices are thought to be morally permissible. Further, the author of this article recommends that, moving forward, a good way to “bridge the two cultures” of animal ethics and animal welfare science is for animal ethicists and animal welfare scientists to focus on ethical theories that are more compatible with animal use, such as theories emphasizing “husbandry” or “care” rather than “respect” or “rights.” This, too, suggests some degree of moral bias.

The issue of moral bias in animal welfare science is one that must be handled carefully. The possibility that some segments of this community are biased toward animal-use practices and/or industry, while it should be taken seriously, should not be taken to suggest that all segments of this community are biased. Indeed, since the animal welfare science community has also produced much research that is critical of current agricultural production systems and laboratory-animal use practices, it is implausible to suggest that moral bias is an issue throughout the field. Furthermore, it might be thought that the investigation of animal welfare in agriculture, research, and other contexts will naturally tend to spring up in environments where these activities take place – this is, of course, the most expedient way to study the welfare effects of animal-use practices. Moreover, responsibility in argumentation requires that we avoid blatant commission of the *ad hominem* fallacy, where a person’s arguments or research findings are dismissed because of supposed

personal biases. Despite all of these qualifications, however, it seems plausible based on the above discussion to worry that *some* segments of the animal welfare science community might harbor a bias on certain animal welfare issues. Because it is not always easy to spot the many ways in which values shape science, careful evaluation of scientific studies on animal welfare should therefore include some assessment of the value judgments implicit in the study and the positionality of the authors.

Summary

This entry has reviewed philosophical and political concerns in the definition and assessment of animal welfare. First, it was argued that animal welfare is an ethical concept at bottom rather than a scientific concept – though the assessment of animal welfare may require scientific study. Second, the entry reviewed various definitions of animal welfare and suggested that a plausible definition of the concept should make reference to an animal's subjective experience. Third, the entry examined the question of whether death harms animals and concluded that the best arguments favor this conclusion, though it still may be the case that death harms humans more under most circumstances. Fourth, the entry discussed how the scientific assessment of animal welfare involves a number of methodological value judgments related to study design and interpretation. Fifth, the entry discussed how the assessment of animal welfare often requires that one weigh harm and benefit against each other and that such judgments are value-laden. Sixth, and finally, the entry discussed how a person's political or moral commitments might inappropriately bias the definition and assessment of animal welfare, thus necessitating a critical stance when reviewing the literature.

Introduction

This entry will explore the significance of aroids (*L. Araceae*) in different cultural settings and regions of the world and examine ethical issues associated with tangible and intangible aspects of aroids in the global food system. Aroids are the world's oldest cultivated crops. All plant parts are eaten, but most often they are cultivated for their starchy underground parts. The plants but also numerous aroid dishes carry a deep symbolic meaning and cultural value in numerous communities in and from Austronesia, Africa, Asia, the Caribbean, Latin America, and the Mediterranean. At present aroids are the sixth most important root and tuber crops and rank fourteenth among staple vegetable crops in the global food system. The Food and Agriculture Organization of the United Nations (FAO) roughly estimates that around 400–500 million people in the (sub) tropics and developing world are involved in the cultivation, consumption, and trade. Simultaneously, aroids are described as “orphan” crops and hardly known in the Western Hemisphere, where, since the mid-twentieth century and the (global) South to North migration, aroids and aroids products became widely available (notably) in densely populated urban areas. In the same century, the food sector evolved into a highly commercialized industrial system and agriculture into agribusiness. Despite being the most widely distributed starchy staple in the modern era (c. 1500–1800), aroids managed to escape from industrialized agriculture with a focus on large fields and monoculture. But as a result of globalization, urbanization, and transnational trade, aroids are increasingly assuming importance as cash crops. In the first decade of the twenty-first century, the global food system has also become increasingly complicated. Concerns about population growth, land use, agricultural biodiversity, small-scale farmers, sustainability, and food

security encompass every area of the world. Root and tuber crops, including aroids, play a considerable role in addressing these issues.

Aroids in the Global Food System

The cultivation, consumption, and trade of aroids are foremost restricted to ethnicities in and from (sub)tropical regions and the developing countries, where 60% of the world's food is produced by around two billion smallholder farmers. In Africa, Asia, and Latin America, the underground parts of aroids are a traditional staple food and main source of energy for millions of people. The vast majority live at a subsistence level or in extreme poverty. Especially in these regions, the cultivation and consumption of roots and tuber crops are projected to grow substantially in the twenty-first century (Scott et al. 2000).

Aroids are of importance in traditional farming systems and of significance for food security in the world's poorest regions and, therefore, described as orphan crops, which are also known as minor, neglected, and underutilized food plants. These crops continue to be maintained by local communities and have received little scientific research and funding. Since the 1990s, research interest in aroids is emerging, and at present a number of governments, research institutions, and nongovernmental organizations (NGOs) are engaged in research projects to preserve genetic diversity and exploit the potential of aroids as a food for the future (Scott et al. 2000; Ramanatha et al. 2010; INEA 2011; Biodiversity International 2012). Research institutions and NGOs consider a better use and conservation of aroids in smallholder farming systems instrumental to improve global biodiversity and food security. Since 2011 the International Network for Edible Aroids (INEA), a consortium of institutions and scientists from various disciplines, applies modern biotechnologies to overcome environmental and other challenges. In the process INEA seeks to increase aroid production and the income of farmers and improve food security (INEA 2011). By focusing on training and technical advice in good postharvest practices and storage methods, the FAO assists farmers to add value to aroids and

thus increase their income from better market opportunities.

Orphan crops not only meet food and nutritional needs; they are also strongly linked to sociocultural preferences and use practices. Food practices and beliefs are among the many differences between Western and non-Western cultures; still schemes to improve food security through aroids often ignore or give very little attention to ethics of non-Western societies at large. In Western society nearly all food is purchased in supermarkets, and most people have no direct contact with farmers. Consequently, not the food westerners grow but the food they eat has become one of the most powerful symbols of who they are (or identity). The physical and mental distance between the farm and plate is less vast in the (sub) tropics and developing world. With an estimate population of three billion people, around two billion people are engaged in farming at a subsistence level; therefore, not only eating but growing and preparing food play a fundamental role in who they are (or identity). These vast cultural differences are not yet well explored nor do they receive the necessary attention. The race to increase global food security often serves as a rationale to deploy modern biotechnologies, intensify production, and increase income. The continuing maintenance of aroids in smallholder farming system indicates that the world's oldest cultivated crops are grown on more direct cultural and moral grounds.

Origin and Nomenclature

Aroids are ancient plants that evolved in swampy areas during the Cretaceous. In this geological period that lasted from about 145 million to 65 million years ago, the first monocotyledonous plants or monocots were formed. Fossil remains of ancient aroids have been found in the tropics but also in the Northern and Southern Hemisphere and temperate regions such as Patagonia (Argentina) and Canada (Bown 2005; Herrera et al. 2008). Aroids can be found on every continent, but the identification of the many different wild and cultivated genera and species is difficult and requires a trained eye (Bown

2005). Since ancient times, aroid genera and species carry a multiplicity of vernacular and overlapping names in various languages and oral traditions. The most dominant term for cultivated aroids is “taro,” which is a derivation from Polynesian languages and frequently used as an inter/exchangeable term for the various cultivated genera (Spriggs et al. 2012). Other terms include tannia, cocoyam, yam, elephant ears, dasheen, eddo(e), tannier, yautia, and malanga (Flach and Rumawas 1996; Elevitch 2011; Ramanatha et al. 2010).

The Aroid Plant Family

The aroid plant family currently comprises of more than 120 genera and about 3750 species of which many are used as food, medicine, animal fodder, ornamental plants, and cut flowers. Several aroid genera, such as *Arisarum*, *Arum* (*Dracunculus italicum*), *Calla*, *Dracontium*, *Monstera*, *Pistia*, *Spathynea*, *Typhonium*, and *Lemna* (duckweed or water lentils), are on record as food, but the five most important aroid genera, cultivated as a crop and collected from the wild but also used medicinal and as animal fodder, are:

1. *Elephant ear* (*Alocasia*) is a genus in excess of 100 species. Common names also include false or giant taro. Elephant ear is usually harvested in between 12 and 24 months after planting, but harvesting is also delayed for up to 4 years.
2. *Elephant foot yam* (*Amorphophallus*) is a genus of more than 257 species; only four species are used as food and medicine. The cultivation is most important in India, Sri Lanka, Myanmar, parts of Indonesia, the Philippines, China, and Japan. The large round subterranean tuber can weigh in between 1.5 and 30 kg or more. The tubers are sometimes harvested after a year, but depending on the variety, elephant foot yam commonly is harvested in between 2.5 and 4 years.
3. *Swamp taro* (*Cyrtosperma*) is a small species of aquatic aroids indigenous to Southeast Asia where it grows wild in swamps, rivers, and lakes. It is most widely cultivated in Micronesia and the western Pacific but also in parts of

Indonesia and the Philippines. Swamp taro is one of the world's largest plants producing an edible corm or tuber, sometimes weighing as much as 100–120 kg. The corm is usually considered ready to harvest between 3 and 6 years but also harvested after 12 months up to 10 years. Stored underground the corms remain edible for many years.

4. *Taro* (*Colocasia*) is the world's best known edible aroid genus. The “eddoe” (*L. Colocasia esculenta* var. *antiquorum*) and “dasheen” (*L. Colocasia esculenta* var. *esculenta*) are the most popular species. “Dasheen” produces a large main corm with small cormels and is primarily cultivated for its main corm. “Eddoe” produces a smaller main corm surrounded by larger, more developed cormels that are the principal harvest. Taro is most often grown as an annual and also cultivated for its edible leaves.
5. *Tannia* (*Xanthosoma*) has two main species, *X. sagittifolium* (L.) and *X. nigrum* (synonym *L. violaceum*), that are cultivated throughout the tropics. Tannia is also cultivated for its edible leaves, commonly grown as an annual (harvested after 9–12 months); both the main stem and the cormels are harvested. Leaving the plant intact, the underground cormels are also harvested (Flach and Rumawas 1996; Elevitch 2011; Ramanatha et al. 2010; Spriggs et al. 2012).

Elephant ear, elephant foot yam, taro, and swamp taro are believed to originate in tropical Asia. From the Indomalaya ecozone, an area between Myanmar and Bangladesh, they spread eastward to other Eastern Asian regions and the Pacific, where the domestication and cultivation of aroids in fields and terraces occurred when rice and wheat were just weeds (Ramanatha et al. 2010; Spriggs et al. 2012). Archaeological evidence on stone mortars and pestles from the Solomon Islands suggests that taro was already in use around 28,700 years ago. Therefore, ethnobotanists and archaeologists consider aroids the oldest cultivated staple crop on earth. Whereas elephant ear, elephant foot yam, taro, and swamp taro originate in Southeast Asia, tannia is the only indigenous American aroid widely cultivated for food. Together with taro, it is the most widely

distributed and consumed aroid (Bown 2005; Ramanatha et al. 2010; Spriggs et al. 2012).

Cultivation and Harvesting

Aroids are primarily cultivated by smallholder farmers on small plots and in a wide range of environments and agricultural systems. The production does not require special horticultural techniques, and fertilizers and pesticides are seldom used. Most aroids are well adapted to moist tropical climates with short dry seasons, and most genera tolerate short or longer periods of dryness (Flach and Rumawas 1996; Elevitch 2011). Elephant ear, elephant foot yam, swamp taro, and tannia are also among the important subsistence crops used in times of food scarcity. Although sometimes seed propagation is applied, vegetative propagation is the most common practice for aroids and involves the removal of cormlets or suckers (pieces) of the “parent” plant. Aroids are cultivated on a wide range of soils, and a large diversity of local cultivars is used in traditional agricultural systems. In home gardens, traditionally aroids are intercropped with numerous other crops. On estates or plantations, they are intercropped with other aroids, corn (maize), plantains (or bananas), common yam (*Dioscorea*), cassava (*Manihot esculenta*), sweet potatoes (*Ipomoea batatas*), and other vegetables. In the Pacific, after the clearing of land via slash burning systems, elephant ear, taro, and tannia are produced in mixed gardens. Polyculture is also applied in agroforestry and for the production of tannia in Latin America and Africa, where the shade-loving plant is considered the most important aroid. In the Indo-Pacific region, historically taro is an important irrigated monocrop. The wet cultivation of taro in freshwater swamps, pits, true irrigation (via water transport systems of canals or pipes), and pond fields (in appearance similar to rice fields or terraces) is among the most ancient and productive agricultural techniques. Wetland taro cultivation is only competed by the similar agricultural system based on rice (*Oryza sativa*) (Flach and Rumawas 1996; Elevitch 2011; Spriggs et al. 2012).

Planting and harvesting of aroids are done by hand and hardly involve mechanization, also

because harvested tubers can easily be damaged and are susceptible to diseases. In general aroid underground parts are harvested at the end of the growing season but sometimes also continuously or partial for home or local consumption. The harvesting of young aroid leaves from home gardens, and for edible purposes, often starts a few weeks after planting (Flach and Rumawas 1996; Elevitch 2011; Spriggs et al. 2012). The collection of aroid leaves (blades and petioles or stalks or stems) from the “wild,” and cultivation as a community food, is a widespread tradition in Southeast and East Asia. In countries such as China, India, Indonesia, Fiji, Nepal, Vietnam, Myanmar, and the Philippines, soft young leaves and petioles of “wild” taro are obtained from uncultivated habitats, in or alongside roads, trails, ditches, ponds, forests, lakes, and streams (Elevitch 2011; Spriggs et al. 2012).

Nutritional Value

All plant parts of aroids are edible. The leaves, stems, and petioles serve as a green vegetable, but they are particularly cultivated for their starchy underground parts. Providing for carbohydrates, the corms and cormels have a similar nutritional value as potatoes. If compared with potatoes, their protein content is slightly higher and about twice as high as in (sweet) potatoes and cassava. Because of the relatively small size of the starch grains, both the carbohydrates and proteins of aroid underground parts are hypoallergenic and easily digested. Furthermore aroids contain minerals, vitamins C and B1 and B2, and niacin. The nutritional value of aroid leaves is comparable with spinach. Apart from rich in protein, aroid leaves are an excellent source of vitamins A and C, calcium, potassium, phosphorus, iron, and folic acid (Opara and Mejía 2003).

Historical Significance

In several areas of ancient China, taro was an important staple crop; its cultivation is dated back to 8000 BC or before. The crop also diffused

westward to Madagascar and Africa and to the Middle East and the Mediterranean where it is cultivated since time immemorial (Bown 2005; Ramanatha et al. 2010). In ancient Egypt taro was among the important wetland crops, consumed as vegetable and used for the production of flour. The flower referred to as ciborium was used as a vessel or drinking cup and is seen on statues of the god Osiris, and the seeds were eaten green and dried. Extensively cultivated in Egypt, Syria, Palestine, and adjacent countries, taro probably migrated to Crete, Cyprus, and Greece where, among others, it is listed among the exotic and rare plants in the orchards of Sicyon, the ancient Greek city-state in Corinth (Peloponnesus), and the nickname of both the goddesses Athena and Minerva. In Virgil's time (the ancient Roman poet Publius Vergilius Maro, 70 BC–19 BC), taro began to be planted in Italy. Using different definitions for the plant and plant parts, e.g., arum, Egyptian bean, cyamos, colocasia or kulkas, pontic, and ciborium, ancient authors such as Herodotus (c. 484–426 BC), Theophrastus (c. 327–288 BC), Dioscorides (c. 40–90 BC), and Pliny the elder (23–79 CE) all referred to taro in their writings (Genaust 1996). Taro is also mentioned in ancient herbals and as an ingredient in several dishes in the *Apicius*, the oldest collection of recipes in the western world, written in vulgar Latin and compiled around the late fourth or early fifth century. The recipes in the *Apicius* reflect the cuisine of a wider group of urban cosmopolitans and thus indicate that the Romans were well familiar with taro and taro preparation and considered it suitable for the palate of many financially secure Romans (Vaneker 2011; Van der Veen 2011). In the modern era (c. 1500–1800), taro was the most widely distributed starchy food plant and during this period was introduced in the Caribbean and Latin America. In later times taro became a less important staple crop and food (Ramanatha et al. 2010). Tannia, the only indigenous American aroid widely used for food, originates in Latin America, where the bulk of the diet of many (pre-Columbian) Amerindian cultures consisted of starchy roots and tubers such as cassava (manioc), sweet potato, and tannia. Although within the archaeological

context the cradle of origin remains obscure, its domestication and dispersal throughout the Americas took place long before Columbus arrived. Excavations at Cerén (El Salvador), for instance, indicate that the ancient Maya cultivated tannia around 600 CE. At the time of the Columbian Exchange, tannia was among the important crop plants cultivated from Brazil to Southern Mexico and in Bolivia and the Greater Caribbean. In the modern era, tannia was introduced in Asia and Africa where it meanwhile is perceived as a traditional crop and food (Bown 2005; Ramanatha et al. 2010; Vaneker 2011).

The Globalization of Aroids

During the modern era, aroids migrated South to South, but in twentieth century and as a result the age of decolonization and growing demand for low-skilled labor and a massive South to North migration, they became available in the Western world. At present Europe and the United States are home to over 100 million migrants of which many come from (sub)tropical areas of the world. Migration is known to affect the dynamics of cuisines and the perception of traditional foods. Apart from a necessity, the continuation of cooking and eating habits from the homeland enables migrants to adapt to new living conditions but also to continue important cultural practices and ways of life. In order to sustain a sense of identity and continuation, migrants living in densely populated urban areas started to revalue aroids. In the process aroids increasingly are transforming from subsistence or poor people's crops into a traditional food with cultural value. Especially in migrant dense areas, taro became widely available, but also tannia can be purchased all year around in ethnic stores; Asian, African, Hispanic, and other tropical markets; natural food stores; and sometimes mainstream supermarkets. Taro and tannia corms and cormels are sold fresh, as well as peeled, frozen (grated), and fermented and as flour. Aroid leaves are commonly sold fresh. Consumed by steadily growing migrant populations, outside of migrants populations,

aroid consumption and consumer familiarity only slowly increase (Vaneker 2011).

The transformation of aroids from subsistence crops into a food with cultural significance increases its economic value. Since the 1920s taro and tannia corms are produced commercially throughout the tropics, including fields in Florida. Since 1988 global aroid production slowly increases and export grows (Opara and Mejía 2003; Ramanatha et al. 2010). Especially West Africa (Nigeria, Ghana, Cameroon, and Ivory Coast) and Middle and Latin America (Costa Rica and Nicaragua) are large producing and exporting regions. Also more often aroid products are becoming available. Fresh or frozen taro and noodles from taro and elephant foot yam are exported from Asia to Asian communities worldwide. West African packages of *fufu* flour, with both taro and tannia flour, can be purchased in African stores around the world. Commercial products from tannia and taro corms include starch for industrial purposes, flour (as a wheat substitute), and fructose syrup for bakery products and soft drinks. Other commercial products from aroid corms include chips (or crisps), breakfast cereals, flakes, and noodles (Flach 1996; Opara and Mejía 2003). Ready-made aroid dishes include Hawaiian *poi*, Surinamese *pom*, and Costa Rican *olla de carne* and are sold in local supermarkets or exported to expatriate communities.

Increasingly farmers in Western societies are turning away from conventional agriculture and agribusiness to grown more profitable “ethnic” crops and other specialty vegetables. To provide migrant communities with taro and tannia leaves, since the 1970s, these are commercially cultivated in greenhouses in the Netherlands. And in order to cater to the “taioba” needs of the local Brazilian community and support struggling farmers, tannia is among the ethnic crops cultivated in greenhouses in Massachusetts (Scott et al. 2000; Opara and Mejía 2003; Bown 2005).

Regrettably the locavore movement, promoting the consumption of locally grown food, does not pay attention to crops migrants perceive as local (food), neither is the carbon footprint of greenhouse gas emissions versus fuel for transport part of current concerns and debates. In addition, the nostalgia for a taste of their homelands makes

migrants reluctant to abandon aroids and replace these with much cheaper available alternatives. In many dishes taro tubers are preferred over less costly potatoes and sweet potatoes and the more pricey leaves of both taro and tannia over spinach. In Europe and the United States, one out of five of the total population is a migrant, often performing poorly paid unskilled labor, but still debates about the costs of foods Western societies perceive as their key staples exclude the perspective of migrants and other ethical issues specific to the food preferences of migrant populations.

Preparation, Significance, and Cultural Value

Although several aroid genera are on record as being consumed raw, most aroids contain oxalic acid, and the acidity of the corm, cormels, and leaves is known to cause irritation of the skin and mouth. Common and ancient techniques to make aroids digestible and denature toxins (the calcium oxalate crystals) are cooking (baking, roasting, and boiling), drying, and fermentation (Ramanatha et al. 2010; Vaneker 2011). The tubers (stem, corms, and cormlets) are prepared in various ways and either washed and peeled before further preparation or boiled or baked with the skin. Preparation methods include boiling, baking, steaming, roasting, pounding, drying, frying, and fermenting. Together with other tropical roots and tubers (e.g., cassava, sweet potatoes, and common yams), aroids are used in soups, stews, and chowders. The tubers are also made into flour or meal for porridges or puddings, breads, and pastries. Common methods for the production of flour or meal include grating and the pounding of raw (fresh) or cooked tubers. The stems of leaves or blades and the leaves are used as a green vegetable and often considered a delicacy (Flach and Rumawas 1996; Ramanatha et al. 2010; Vaneker 2011).

In recent decennia, in Western societies, different cuisines started to coexist and began to overlap and mix, and increasingly “exotic” foods and ethnic cuisines are adopted. But apart from a handful of traditional dishes, relevant literature

and cookbooks in Western society still hardly provide for aroid recipes and information. The standard advice is even aroids and other (sub) tropical roots and tubers are inter/exchangeable, and the lack of cooking advice and recipes indicates the unfamiliarity of westerners with aroids (Vaneker 2011).

Aroid preparation techniques and recipes are foremost orally transmitted, and traditional ways of preparation largely remain unrecorded. And even though there are no inventories of the many surviving recipes and traditions, increasingly non-western communities share traditional recipes via websites and blogs on the Internet, showing that the cultural value of aroids keeps evolving in response to its environment and continues to provide communities and groups of people with a sense of identity and continuity.

Aroids are older than humanity and therefore only gradually became part of culinary traditions of countless groups and communities worldwide, whose ethical values most often have evolved within religious traditions. Dishes and rituals still in circulation encompass living expressions and traditions that countless people have inherited from their ancestors and transmitted to their descendants, in most cases orally. Not only in ancient Egypt and ancient Greece aroids became part of religious traditions, until today aroids are sacrificed to deities or commemorated in mythological stories. In India the antiquity and importance of taro is underlined by the rich diversity of traditional recipes and preparation techniques. Taro cormels, corms, leaves, and petioles are consumed in a wide variety of traditional Indian dishes, such as curries, chutneys, pickles, and stews and are used for ayurvedic or medical purposes. Taro is an important offering in several important rituals and festivals for major Hindu deity's such as Krishna and offered to the deity in the famous Jagannath Temple in Puri. On special occasions in Gujarat and other northern Indian states, taro leaves are prepared and consumed. Commemorating the baptism of Christ, taro is the main dish for Egyptian Copts on *Eid el Ghutas* (Epiphany). It is similarly deeply rooted in Japanese food culture where the "satoimo" (meaning village or home root or tuber) plays a central role in

small-scale farming systems (Ramanatha et al. 2010; Misra and Nedunchezhiyan 2012).

Taro cultivation and consumption are ancient in several Austronesian communities (e.g., Pacific region and Hawaii), known as *dalo*, *kalo*, and *talo*; all over the region the corms are grated or pounded into starchy, fermented pastes or puddings referred to as *fakakai*, *fai'ai*, *feikai*, *loloi*, *poke*, *po'e*, *poi*, *roroi*, *sua*, *tukituki*, *taufolo*, and *vaihalo* and an integral part of Polynesian feasts. Hawaiians believe that eating *poi* unites people but also supports the family (*ohana*) and shows appreciation for the ancestors (*aumakua*). In Hawaiian mythology, taro (or *kalo*) is believed to be the greatest force of life of all foods and linked with creation. According to the legend, the plant grew from *Hāloa-naka*, the first stillborn son of *Wākea* (father sky) and *Papa* (mother earth). After the burial of *Hāloa-naka*, a second child *Hāloa* (everlasting breath) was born, and Hawaiians consider themselves descendants from *Hāloa* (Vaneker 2011).

Both taro and tannia are a prominent staple in the diets of numerous West African communities where aroids and other starchy tubers and roots – alone or in combination – are used for the preparation of the traditional staple dish *fufu* or *futu*, a pounded porridge or pudding. Other common African preparation methods for aroid corms and/or cormels include boiling whole with the skin, pounding, roasting, fermenting, and baking. Cubans consider tannia, known as "malanga," the queen of the stew vegetables. Fidel Castro is on record saying "¡se ha olvidado la malanga!, a pesar de las veces que hemos dicho que si no hay nada que comer comeremos malanga (APLAUSOS)" ("the malanga has been forgotten!, despite the time we have said that if there is nothing to eat we will eat malanga (Applause)"). Tannia is a prominent ingredient in the Cuban stew *ajiaco*. Similar stews or soups with root vegetables, pieces of meat, fish, or chicken are prepared in households all over middle Latin America. In Costa Rica the popular multiethnic dish is known as *olla de carne*, in the Dominican Republic as *sancocho de siete carnes*, in Colombia and Puerto Rico as *sancocho*, in Panama as *sancocho de gallina*, in Haiti as *bouyon* or

bouillon, Venezuela *aspicadillo llanero*, and in Jamaica, Antilles, and Guyana as *pepper pot*. All over the Caribbean deep-fried fritters (such as *frituras*, *friturita de malanga*, *malanga chips*, *alcapurrias*, *accra*, *frituras de yautía*, and *buñuelos fritos*) with tannia are prepared. In the Caribbean the leaves of tannia and taro are known as *callaloo*, *calalu*, *calalou*, *callilu*, and *callalou* or Caribbean spinach. Boiled and pureed, they are a central ingredient for a popular one-pot dish (from green vegetables) and known by the same name. In the Surinamese community in Suriname and the Netherlands, taro corms are used in soups, and the leaves (known as *tajerblad*) are among the most popular green leafy vegetables. The main corm (stem) of tannia is a central ingredient in *pom*, the national oven dish prepared with grated tannia and stewed chicken in a sauce. In recent years, outside the Surinamese community, the oven dish rapidly gained popularity in the Netherlands (Vaneker 2011).

Swamp taro was a popular food crop throughout Southeast Asia in the early twentieth century and still an important crop in the Pacific. The underground corm is the primary edible product and highly valued in parts of Micronesia where large tubers are presented and offered to honorable guests. The young leaves, stalks, and inflorescences are also on record as vegetables. In Southeast Asia and Micronesia, swamp taro leaves are used in dishes and as a wrapping material for food prepared in the pit or earth oven. In Asian cuisines aroid corms and leaves are often prepared with coconut milk. In the Philippines taro leaves (blades and petioles) are preferred over the corms and widely used in cooking. Taro leaves are also consumed in Indonesia, Fiji, Nepal, Vietnam, and Myanmar (Flach and Rumawas 1996; Ramanatha et al. 2010; Elevitch 2011; Spriggs et al. 2012).

Elephant foot yam is the most important cultivated aroid in India. On Diwali (or Devali), one of the most important annual Hindu festivals, it is consumed widely in northern India. The tuber is considered a delicacy and also used for the preparation of pickles and indigenous medicine. Of wild species the sprouts, petiole, corms, cormels, stem, and even the unopened inflorescence (a typical

feature of aroids) are collected for medical, ayurvedic, and nutritious purposes. The tuber is boiled, baked and fried, and used in curries and the preparation of gruel (Misra and Nedunchezhiyan 2012). In India and Bangladesh, the mature stem of elephant ear is peeled, cut into pieces, and eaten as a cooked vegetable, usually with tamarind juice and in curries or stews. In the Pacific the stems are roasted, baked, or boiled and eaten as a carbohydrate or starch. Older stems require prolonged cooking, and the leaves are eaten as well (Flach and Rumawas 1996; Elevitch 2011).

The above practices and uses show that aroids are an ancient crop and food with all kinds of symbolic and other meanings. Millions of people in and from the (sub)tropics and developing world maintain aroids as tangible and intangible cultural heritage. Simultaneously, and despite their ancient and evident importance in the global food system, the orphan crops are largely linked to subsistence agriculture and local expressions of culture. Post-war globalization, migration, and urbanization have had a very different outcome in the many different aroid-“producing” and aroid-“consuming” regions and cultural and economic settings. The wide availability of aroids and aroid products in Western society has an ongoing impact on culinary uses and production. In addition, the effectiveness of food security schemes to relieve hunger, increase global food security, and maintain agricultural biodiversity transcends tangible values and the fundamental moral and political responsibility to feed the hungry. Aroids are foremost grown because of sociocultural preferences and use practices; subsequently culture and morals play an important role to maintain, manage, and safeguard the crop that has been part of the development of human civilizations and still is part of living cultural expressions. The vast cultural differences and worldviews that exist between governments, research institutions, NGOs, and the poorest and most vulnerable people are an ethical challenge. Apart from a contribution to global food security and biodiversity, bridging the existing gaps will provide everyone growing and eating aroids with “. . . a standard of living adequate for the health and well-being of himself and of his family” (United Nations 1948).

Summary

This entry addresses the history, distribution, cultivation, and importance of edible aroids, or taro, in the global food system. Aroids are a little known ancient crop and are foremost maintained by farmers in small farming systems in the (sub) tropics. Since time immemorial aroids but also aroid dishes carry a deep symbolic meaning and cultural value in communities in and from Austronesia, Africa, Asia, the Caribbean, Latin America, and the Mediterranean, where culinary knowledge is transmitted orally. Since the mid-twentieth century and especially in migrant dense (urban) areas in the western world, aroids and aroid products are becoming more available.

Artisanal Food Production and Craft

Suzanne Cope
English Department, Manhattan College,
Riverdale, NY, USA

Synonyms

Craft; Pickling; Preserving; Small batch; Traditional food preparation

Introduction

The word “artisanal” has regained a foothold in the US food vernacular and is being used to describe many food and beverage products like pickles, cheese, jam, and gin that have been populating the shelves of specialty shops and crowding tables at farmer’s markets since the start of the new millennium. Like so many similar monikers that have been adopted to connote a specific sense of values in production or quality, such as “natural” and “green,” the word is not regulated and has since been used by large corporations to describe industrial- or mass-produced

goods such as crackers, potato chips, and pizza (Donnelly 2012). Thus a debate has ensued about the true meaning of the term and what, if anything, should be done to ensure its veracity.

The term “artisanal” has its roots in the Italian word “artigiano,” meaning artisan or craftsman, which has its own etymology from the Latin “artitus” which means instructed in the arts. Thus, the term is understood to mean someone who makes a specific product or provides a specialized service with a high degree of skill or art, stemming from the Old World culture whose economies relied upon local artisans for everything from bread to furniture. In present vernacular, “artisanal” is used, in its broadest sense, to describe a product that is made by an artisan and is most properly used to indicate something that is handmade, unique, and high quality – often the very opposite of mass-produced. It was the reaction of some to the industrialization of US culture’s food system – with its cheap meat and dairy, increasing monoculture and proliferation of processed foods – that helped spark a growing revolution in the last few decades back towards personal gardens, small farms, and traditional forms of food preparation and preservation, both in the home and in the marketplace, which prompted a resurgence of interest in artisanal goods and methods.

Historically, the term artisanal has been used to refer to a wide variety of goods and services, including some edibles. However, only since the start of the new millennium has the term been reclaimed within the vernacular to describe primarily food products, generally referring to those that have been made using traditional methods, often by hand and with attention to quality. Artisanal goods are sometimes referred to as “craft” goods, referring to the skill needed to make these items, or “small batch” – a term that originally was used to describe high-end whiskeys that represented the highest quality of a batch and were closely tended to by artisans, but has come to be inclusive of all goods that are made with the same attention to ingredients and skill. Thus, with this increase in artisanal food production for both personal and commercial use, the debate surrounding this category of food has focused on

determining a true definition of what an artisanal good is and whether an embracing of more – and often more expensive – artisanal goods in the marketplace is a move forwards in regard to food culture, safety, and security.

History

The term artisanal was originally used to refer to primarily to nonfood-related goods and skills, and evidence of an artisan class can be traced back to Ancient Egypt where workers specialized in jewelry making, carpentry, and sculpting, among other skills. During the medieval period, when artisan guilds were created to help organize and maintain standards of these workers whose livelihood and status depended on their specialized skills, the western societal role of artisans was elevated beyond that of a slave or laborer and seen more akin to an artist. The artisan guilds of the Middle Ages included bakers and butchers, as well as experts in other food and nonfood-related skills. Many of these skilled workers continued to be a vital part of western society into the modern age. The food artisans in particular – through trial and error, new understandings in science and technique, and technological advances – continually improved their craft and helped define their role in their local and regional food culture. The result was specialty artisanal food that developed in areas and regions around the world, such as the refined smoked sausages from Germany, cured prosciutto from Italy, or aged cheese from Spain, as well as many other examples of food local to a region prepared or preserved used traditional methods unique to an area or culture.

What made the artisanal food culture in the United States unique, however, was the ways that the population learned to adapt to the available foods and climate of the New World and the eventual melding of cultures and skills, starting with what the settlers learned from the Native Americans in the 1600s and continuing with the immigration of many different cultures from Europe, Asia, Africa, and beyond into the 1900s and through to the present. All of these cultures brought their own food preparation and

preservation skills and methods, inspiring the culture and adapting to the region, creating a unique artisanal food culture in the United States, noted for its independence and individuality, both for commercial sale and personal use (Eden 1999).

In the United States, artisanal food culture was evident in many towns and neighborhoods from the earliest settlers, even if the term artisanal was not often used. By the twentieth century, however, increased technological advances spurred cultural changes, fewer homes had personal gardens, and women in both urban and rural areas were more likely to purchase staples like pickles, cheese, and canned goods at a store rather than make them at home, and these purchased goods were increasingly mass-produced rather than made by local artisans (Levenstein 1988).

Further technological advances and the two World Wars also greatly influenced the movement towards mass-produced convenience foods. The wars brought cultural changes, such as more women in the workforce, which resulted in less time spent on food preparation at home. Packaged foods like TV dinners, using technology developed for soldiers, became popular, and the introduction of fast-food chains made eating out more accessible (Shephard 2000). Agricultural moved towards monoculture as well, which, along with the increase in mass-produced foods, helped push culinary trends towards flavor homogenization. Further, after the rationing of the Second World War, feeding people food of uniform quality and safety becomes the highest priority, rather than distinction of flavor (Roudot 2004). Skilled household food preparation and preservation activities from a generation prior, such as canning, pickling, and cheesemaking, were becoming increasingly rare in urban and suburban homes, with more consumers choosing to buy the versions available at the local grocery store. Likewise, many local artisanal food producers went out of business as shopping habits moved towards the larger supermarkets and away from specialty retailers. With this move towards mass production, prices dropped for the average consumer, as did the variations in products, quality, and proliferation of food preparation and preservation skills.

The “counterculture” movement of the 1960s sparked interest in a growing segment of the population in gardening, vegetarianism, and food co-ops and brought attention to the potential health risks of the red meat- and preservative-heavy meals that had become prevalent in US homes. This influenced a shift in culinary tastes that gained speed in the 1970s when Alice Waters began to popularize “Californian” cuisine that emphasized fresh, seasonal ingredients, and traditional preparation methods. This movement began to grow into a resurgent interest in personal gardens and small-farm production, as well as traditional food preparation and preservation methods, which evolved into a “back-to-the-land” movement in the 1980s (Paxson 2010). International travel also hastened the shift of cultural tastes, with sophisticated eaters returning from their trips interested in increasingly diversified flavors and more in touch with the artisanal foods that they encountered in countries like Italy, which had not moved towards the pervasive mass production of popular foods like the United States.

This cultural shift was apparent in a small, but influential portion of the population into the new millennium. As the first rumblings of the recession were being felt in the mid-2000s, so continued a rise in family gardens, preserving, and artisanal food production, as evidenced by the dramatic rise in cheesemakers, whose numbers doubled since 2000 (Paxson 2012). This interest in artisanal edibles grew alongside the interest in locally sourced food. In fact, since the US Department of Agriculture (USDA) began publishing the national directory of Farmer’s Markets in 1994, the number of farmer’s markets had more than quadrupled nationally by 2012 (United States Department of Agriculture 2012). With these new markets came new customers interested in local produce and products made from ingredients and by people, they felt adhered to their same values of environmental and economic sustainability. In addition, these markets provided a literal marketplace where small and start-up businesses could sell their products and started to gain customers relatively easily, because of the lack of need for distributors, and for a relatively low start-up cost. Also, at this time, people

looking to cut costs started to grow their own food, and sales of seeds spiked in 2007, with the National Gardening Association noting that more than 43 million households grew their own food in 2009, an increase of 19% from the year before (Sanburn 2011). Now, not only were more households harvesting their own produce and, presumably, looking for ways to preserve their bounty, but also more people were looking for work. This led to more people trying traditional preserving and preparation methods in their home, a greater cultural interest in homemade, local, and high-quality food products (Muller 2010), and an increased number of people starting food-based businesses (Casserly 2012). These businesses ran the gamut from a glut of food trucks serving mostly urban areas to smaller-scale organic farms to specialty foods like high-end baked goods, often boasting of as “artisanal” aesthetic of preparation and quality. Many of these businesses were envisioned to cater to the new “foodie” culture that sought high-quality, handmade, and often environmentally conscious food options. This new trend in artisanal foods can be seen most prominently in the recent rise of artisanal cheese, pickles, fruit preserves, charcuterie, alcoholic spirits, and other similar small batch purveyors. The dominant narrative in each of these industries is a desire to reclaim what the makers believe are the original, traditional, or true essence of each product – and its endless variations – because of the vast dominance of mass production that each product had endured over the course of the twentieth and early twenty-first century.

Debates

While artisanal food production and craft had long histories in many countries outside of the United States, the larger culture of artisanal foods is relatively new in this country. While there have been some artisanal food makers who have retained a tradition of their craft for generations, unlike in Europe, most food artisans are relatively new with the rise of artisanal products increasing sharply after 2000. These goods may draw heavily from Old World traditions, but pride themselves on

individuality. However this variety of craft products and techniques can mean the dilution of the understanding of the term artisan. Unlike Europe's highly regulated cheese industry, for example, the American Cheese Society asserts a definition of artisanal cheese but has no power to police that their members use it correctly. The European Union has rules about process and ingredients in various artisanal goods, such as cheese, and other countries, like Italy, have similar regulations to preserve the quality and identity of other traditionally made products, such as meat, wine, cheese, among other foods (Gudrais 2010). Thus, the primary debate within the artisanal food community surrounds the true definition of the term and what, if any, regulation should be in place to preserve it.

Various organizations, craftspeople, and food writers assert that a true "artisanal" food product is one made by a skilled craftsman, using high-quality ingredients and a mastered, often traditional, technique (CUESA 2006). Some also assert that artisanal foods can only be made in small batches and with ingredients that are sustainably sourced. However, with the rise in popularity of artisanal edible or potable goods come stories of artisans who initially produced all of their goods by themselves using ingredients that adhere to the strictest of values, but who have expanded to include multiple employees, more readily available produce or other ingredients, automated methods such as mass-processed heat preserving or labeling. The question remains of when a good ceases being artisanal, even if it follows a similar recipe or technique of a small batch good, but on a larger scale. Some argue that a good retains its artisanal descriptor as long as the artisans themselves are still ensuring that the more nuanced mixing, tasting, and quality control are to their standards. Others cite any form of automation or any deviation from traditional methods as unworthy of the artisanal moniker. Only the cheese industry has a somewhat standard, although unenforced, definition of artisanal cheese, which is understood to mean a product made primarily by hand, in small batches, with attention paid to the quality of the ingredients and the skills used in production (Raskin 2012). This also represents the overarching general

understanding of the term by the consumers, food writers, and producers who are familiar with this segment of the market. Thus, while the average consumer may not be concerned with the debate surrounding the term "artisanal" as used by corporate marketers to describe clearly mass-produced items like pizza or potato chips, the numbers who do seek out specifically "artisanal" goods – the National Association for the Specialty Food Trade (NASFT) conducted a study in 2011 which found that 26% of specialty-food consumers seek out artisan products – are growing making the debate over standardization of this term even more pertinent and could lead to misrepresentation of the true nature of products and the devaluing of artisanal goods and methods.

With the consumer desire for artisanal goods is growing and the relatively easy entrance into this market at community spaces like farmer's markets comes the concern of food safety. Numerous artisans cite the often arduous safety or legal regulations that have been a detriment to their growing business, with a great number of craftspeople admitting that they began their business in their kitchen or some other unregulated and illegal space. Most food safety laws are regulated at the state level, although many are similar and include the need for food sold for public consumption to be produced in a certified commercial kitchen, with other frequent requirements including the need for a food processing license or lab tests to ensure food safety. Some exceptions to these laws include allowances for farmers who process produce they grow or "non-potentially hazardous" items to be produced in home kitchens (Gansky 2012). Many artisanal producers note the high price of these regulations – which can reach into the thousands – and cite this as a major burden for starting a business and staying profitable. They have lobbied for more changes to the "cottage food laws," as they are known, which have resulted in more than thirty states creating allowances for the sale of small batch food items, often limiting the types of food that can be produced and sold and putting a ceiling on allowed profits (Andrews 2012). However, proponents of keeping food safety laws strictly in place note the long history behind these regulations, which historically have greatly reduced illness from food produced in unsanitary

environments or through questionably methods, and cite the need to keep standards high to ensure the integrity of public health.

Another issue faced among artisanal food producers is whether the term encompasses a specific value system of environmental ethics. Many small producers begin with a commitment to source their ingredients seasonally, organically, or from local farms, while others merely put an emphasis on self-assessed “quality” raw materials. These purveyors note that this is borne out of the true intent of many artisans throughout history, who were fully integrated with every step of procuring and creating their product, such as illustrated via the strict regulations on ingredients of artisanal foods in Europe, where there are numerous continent- and countrywide rules on the ingredients and methods necessary for proper labeling of specific artisan-made goods, such as types of cheese, sausage, or wine. Some artisans argue in favor of a more exclusive definition of the term, looking to a study that cited an understood level of quality and environmental consciousness in a good labeled “artisanal.” This research looked at the artisanal food culture in Ohio to determine the definition and motivations of artisanal food producers and corroborated a commitment to handmade aesthetic, quality, and environmental concerns – with ingredients often organic or locally sourced (Caricofe 2011). These findings echo what other artisans in favor of a more exclusive definition of the term argue. Opponents note, however, that Americans pride themselves in their independence and would resist additional bureaucracy, with even the large artisanal cheese industry preferring not to pursue regulations, offering instead standard definitions only as guides for labeling (Gudrais 2010).

Further, the issue of environmentally conscious sourcing as part of the definition of an artisanal good can be complicated. Shipping heavy jars, or perishables like charcuterie and cheese, can increase the carbon footprint or call into question the often initial business philosophy of environmental sustainability. The true environmental and health costs of nonorganic and nonlocal goods are often debated, with others noting that high-quality ingredients can be environmentally sustainable, even if they do not share these distinctions

(McWilliams 2009). Likewise, not all artisans put high priority on organic or local ingredients or handmade techniques, asserting that promoting artisanal goods made with whole ingredients, like dessert topping made with fresh cherries – even if with the inclusion of sugar – and less processed or unnatural ingredients like high fructose corn syrup and food dye, is beneficial to consumers and the environment overall, even if the ingredients are not sustainably sourced or the production methods used are sometimes automated. These proponents cite that anything that keeps traditional preservation methods alive, and goods with fewer preservatives and more produce and whole foods in demand, is a positive outcome (Raskin 2012).

Along with environmental sustainability comes the issue of business viability. Some artisans note that they feel pressured by some consumers and fellow craftspeople to keep production as small and handmade as their business survival will allow, sometimes even eschewing automated chopping or mixing machines. Strict adherence to completely handmade can result in higher prices, more barriers towards expansion, and issues of business sustainability, depending on the industry. This reality of business sustainability and the related issue of affordability are issues that many artisanal producers deal with. For the home artisan, whether the material and time required to make a product for personal consumption is worth, it is a personal decision, akin to a hobby or based in preserving traditions, and is worth a higher cost. For others, using raw materials from their own farm or garden, or purchased cheaply in season, making a large amount of an artisanal good for personal use and perhaps to trade with others in their community, is cheaper than buying the goods at retail. However, from a business perspective, often the real calculated cost of selling a jar of artisanal jam or pickles can be many times the price of the mass-produced version to reflect the true price of high-quality produce, packaging, and manual labor. While some consumers are willing and able to pay that amount, many artisans note that lowering the cost of their goods can improve their profitability and overall ability to provide what they consider higher-quality foods to a larger population, making a case for a more liberal interpretation of the

definition of artisanal production. Those in favor keeping the term artisanal highly defined or exclusive would note that any dilution of the term would create a slippery slope resulting in lower-quality products and lost culture or methods that some artisans care deeply about retaining.

Despite these debates over safety, sourcing, and costs, the proponents of artisanal food – both produced for profit and also for personal use – note the unquantifiable positive effect of community building. This can be seen through the exponential growth of farmer's markets that sell artisanal goods in addition to produce, community classes teaching traditional production and preservation methods, and the myriad first person accounts of small batch producers who cite the help of friends, family, consumers, and even other artisans as helping them refine their process and build their business.

Summary

There is no denying that artisanal food production has long been an integral part of global food culture. With increasing industrialization in the western world in the late 1800s and early 1900s, the number of artisans – creating edible goods for both commercial and personal use – dropped, and mass-produced food became more popular in the vast majority of households. However, the past decade has seen a rapid return to these traditional methods of food production for a number of reasons, including the desire to explore and preserve tradition and the increased consciousness about the quality and provenance of one's food. For commercial artisans, there are barriers to entering this increasingly crowded marketplace, including the cost of licenses and fees to operate a certified food production business and the increasing dilution of the term "artisan" through large businesses who seek to cash in on this growing trend. However, even with artisanal goods priced at a premium over similar mass-produced items, growth in this sector of the market is still robust, which seems to indicate that the consumer interest in true artisanal goods – and the values that these products often embody – is only increasing.

Asian Cuisine: Ethical Considerations

Walter F. Carroll
Sociology, Bridgewater State University,
Bridgewater, MA, USA

Introduction

Numerous factors shape decisions about what to eat, including region and geography, nationality, social class, ethnicity, and – central to this piece – ethical considerations.

Ethical belief systems influence not only what people eat or do not eat but also how people eat

and with whom they eat. Other food- and cuisine-related issues having ethical implications include hunger and food security, shifting diets and their repercussions, and sustainability.

This piece focuses on South Asia, especially India, and East Asia, primarily China, Japan, and Korea. China features some of the world's oldest cuisines, and they have had an enormous impact on other countries – especially in East Asia – in terms of ethical/religious belief systems and their impact on food. I also briefly consider mainland Southeast Asia, especially in terms of the influence of India or China. This omits large areas of Asia, such as the so-called Middle East, and other areas in Southeast Asia. Asia is an incredibly diverse area with a wide range of foods and cuisines. Even within nations, there is incredible diversity. India and China themselves are each comparable to the continent of Europe in many ways, including diversity of foods. Sen (2004: xviii) cautions, “there is no national cuisine in India or even a single national dish.” This is true of China as well.

There are conflicting definitions and debates over the meaning of cuisine. One useful definition emerges from Pettid's (2008: 10) history of Korean food. Cuisine refers to how

Cultures manipulate and transform potential food-stuffs into what these cultures consider proper food. Thus, what makes Korean foods ‘Korean’ includes the detailed processes that Koreans use to transform various raw materials into food that is culturally considered to have been prepared correctly. In conjunction with the manner of preparing food are the cultural practices that determine what can, or cannot, be eaten, the manner in which meals are taken, and the social significance attached to various foods.

This definition makes it clear that cuisine is related to a variety of issues related to food, including food preparation, beliefs, and consumption. In this sense, cuisine refers to what Albala (2012: 1) defines as food culture, “the entire set of beliefs and practices surrounding food, agriculture, distribution, and consumption and any topic related to food.” This approach is adopted here.

Ethics is ultimately about values and value conflicts. Introducing *The Philosophy of Food*, Kaplan (2012: 9) suggests that food “is about

serious things like hunger and malnutrition, diabetes and heart disease, eating and being eaten. It is a profoundly moral issue. It always has been. Even ordinary, everyday acts of cooking and eating are forms of ethical conduct.” Throughout history, belief systems have prescribed what and how to eat, at the same time as they proscribe other choices. Therefore, this piece will examine the genealogy of important Asian belief systems and their relevance to food. Kaplan suggests that in addition to questions about what we should eat, food ethics raises questions of how we should eat and whether or not to eat meat. The question of meat eating or vegetarianism is central to ethical considerations on Asian cuisine, as are ethical questions related to hunger, health and well-being, and sustainability.

Origins and History

Since humans moved out of Africa and into other parts of the world, food has been central to our survival. The earliest human groups subsisted on gathering and hunting. It seems likely that the differentiation of different types of food had not yet started. Differentiation and stratification within these groups were also minimal. There are various theories of the role that food played in the development of modern humans, with some suggesting that it was an early reliance on meat. Richard Wrangham (2009) famously hypothesizes that cooking is a central factor, perhaps the central factor, in human evolution. Fernandez-Armesto (2002) suggests that the history of food can be seen through a series of culinary revolutions.

The first revolution is the invention of cooking, which fits with Wrangham’s ideas. In the second revolution, humans move beyond seeing food merely as subsistence and begin to attribute meaning, often religious or superstitious, to food. Ethical beliefs about food surely emerge from this transformation. His third revolution – the “herding revolution” – deals with the domestication and breeding of some animal species. This is followed by a revolution in developing agriculture. The fifth revolution refers to the beginnings

of the stratification of people and food in increasingly hierarchical human groupings. Differences between the food of the elites and the food of the common people are central features of cuisine after that. Fernandez-Armesto’s sixth revolution is the inception and spread of long-distance trading and is “the ecological transformation of the last 500 years, which is usually called the ‘Colombian Exchange,’ and the place of food stuffs in it.” His final revolution is the industrialization of the last several centuries.

In developing this scheme, Fernandez-Armesto makes fascinating arguments about the history of food. Although his approach provides an overall orientation to food history, a less detailed periodization of revolutions can be useful. The first, the Agricultural or Neolithic Revolution, marked the development of agricultural production in about 9500 BCE in the West and about two centuries later in China (Morris 2010). This shift from food gathering to food production enabled and required basic changes in human social organization. One such change is indicated by noting that this revolution is also called the First Urban Revolution. The new mode of food production made large human settlements possible, something that was not supportable for nomadic bands of hunter/gatherers. It depended on the development of social organization characterized by an enhanced division of labor and increasing hierarchy and stratification. Religious and government specialists were able to live based on the cultivation, gathering, storage, and control of food by other groups. This marks the beginnings of differentiation of foods among various groups, a differentiation that was often justified by appeals to religious or other belief systems. It also signaled the onset of developed hierarchies in human societies.

Religion and Food Choices: India

India is one of the most diverse countries in the world. The diversity includes food, as mentioned above, but also encompasses religion and ethnicity. India is home to numerous religion traditions, three of which originated there, and each has

beliefs about food that have ethical consequences for cuisine. In addition to Hinduism, Buddhism, and Jainism, which all developed in India, other religions have played an important role in India throughout its history. For example, India has the third largest Muslim population in the world. Other groups such as Christians, Jews, Sikhs, and Parsis have been important as well, but here I focus on Hinduism, Buddhism, and Jainism and their effects on cuisine.

It is not surprising given the centrality of food to people's lives that ethical considerations based on these belief systems would affect food choices. As Collingham (2006: 4) argues:

Each of the religious communities on the Indian subcontinent is distinguished by their particular food taboos, especially with regard to meat. Thus for example, Christians will eat virtually any meat or fish. Muslims will eat most meats, including beef, but avoid pork. Jains are usually strict vegetarians, and sometimes even avoid red foods, because they are the color of blood. Hindus will not eat the flesh of the sacred cow.

There are exceptions to each of these. Economist Amartya Sen, quoted by Colleen Sen (2004: xvii), makes the point even more strongly when he notes that one cannot understand any aspect of Indian society, including food, "without seeing the extensive interactions across barriers of religious communities. These include Hindus and Muslims, Buddhists, Jains, Sikhs, Parsees, Christians, Jews, and even atheists and agnostics."

But it is not just religion that determined what was appropriate to prepare and eat. "In traditional India, what and how people ate was inseparable from their religion, the life-cycle stage, town and region, caste and/or social status, family traditions, health concerns, and spiritual beliefs" (2004: 29). The religions themselves were not monolithic. Although each had, and has, its own rules about what to eat, there are numerous sects and subgroups within each religion, and they each have their own food prescriptions and proscriptions (Sen 2004).

Hinduism is the third largest religion in the world. Not created by one person, it is a syncretic belief system characterized by a wide variety of beliefs and sects. Hinduism developed during the

period 1000–500 BCE and with it came a caste system which divided people rigidly in all areas of life, including food and eating. Although the Aryans, who had developed Hinduism, were not vegetarians, an aversion to killing and eating meat, especially cows, had developed by 1000 BCE. Sen (2004) suggests several reasons for the emergence of this move away from beef. One important factor may have been how valuable cows were in a variety of ways, such as plowing, giving milk, and producing manure used for fuel. Religious reasons – such as the development of beliefs in reincarnation – were also important. Because humans can come back as animals, the idea of slaughtering animals became less attractive and ethical.

It is not only what to eat that constitute moral and ethical issues in Hinduism but also how food is prepared, handled, and served. For Hindus, "in this world and beyond, the cosmic moral order (dharma) regulates the availability of food to all creatures" (Khare 1992: 5). In India, food is, among things, a moral substance. Many of the distinctions among types of acceptable foods and many of the rules about who can eat what and with whom have declined in significance in recent years, especially for urban dwellers. However, vegetarianism remains important, although there are many gradations of meaning of vegetarianism. Earlier estimates were that 25–30% of Indians are vegetarians (Sen 2004), which would make them the largest concentration of vegetarians in any country, given India's population size. More recent research suggests that widespread perceptions of India as a vegetarian country are not borne out by the results of the 2014 sample registration system (SRS) baseline survey carried out by the Indian government (Bose 2016, Registrar General of India 2014). Keeping in mind Colleen Sen's statement that there is no Indian national dish and reminding us of the variability of food in India, there is much variability of meat eating in various Indian states.

Islam also has a significant presence in India, with the world's second largest Islamic population. The key restrictions on food in Islam are the prohibitions against eating pork and drinking alcoholic beverages. Meat that is slaughtered

and prepared according to Islamic regulations is called *halal*.

Two other important religions – both of which have major ethical implications in regard to food – originated in India in the sixth-century BCE: Jainism and Buddhism. In Jainism, founded by Vardhamana Mahavira, the central doctrine “is that all nature is alive” and should not be harmed (Sen 2004: 10) thus leading to the doctrine of *ahimsa*. The term means nonviolence and stresses the avoidance of harm to living things. The concept is also important in Hinduism and Buddhism. Given their strong adherence to this doctrine, it is not surprising that for Jains eating meat was considered abhorrent and they are strict vegetarians. The Jain food proscriptions may well be the most rigid in the world, encompassing not only “meat, fish, and eggs, but thirty-two things that are believed to contain the germs of infinite life” (Sen 2004: 34).

Buddhism was founded in India by Siddhartha Gautama, later known as the Buddha. He emphasized moderation in all areas of life, including food. Although Buddhist monks were vegetarians in their monasteries, when they traveled and begged for food, they ate whatever was offered to them. Today Buddhists make up less than 1% of India’s population (Sen 2004). Although Buddhism has played an important role historically in India, it has arguably had more important effects beyond India. From India, Buddhism spread to China and from there to other parts of Asia.

Religion, Ethical Systems, and Food: China

In China, food choices and ethics were most affected by three sets of belief systems or ethical codes. In addition to Buddhism, from India, two indigenous belief systems – Confucianism and Daoism – shaped food ethics in China. Other religions and belief systems, such as Islam and animism, also played important roles, but the three listed were most influential. Albala (2012) suggests that Chinese food and eating were shaped by the three traditions of Confucianism, Daoism, and Buddhism. It is important to keep in

mind that Chinese food and eating patterns were and are diverse.

Confucianism was derived from the writing of Confucius (called Kongzi in China) who lived 551–479 BCE. He emphasized social harmony based on one’s place in an ordered society and an awareness of one’s obligations to those above and responsibilities to those below one in the social hierarchy. This started at the level of the family with children owing filial piety to the father, who was seen as the household head. The father in turn had obligations to those above him and those eventually reached to the top level of society. Properly followed this awareness would enable life and society to function smoothly. “This translated into a fully codified set of manners, a way to avoid potential conflict, including at the table” (Albala 2012: 44). Albala notes that this explains why the Chinese developed and used chopsticks and did not use potentially dangerous implements such as forks and knives.

Daoism, founded by Laozi in the sixth-century BCE, emphasized the appreciation of nature with a focus on simplicity and beauty. Albala (2012: 44) suggests that Laozi’s most important contribution to Chinese “culinary culture is the espousal of a simple diet tied closely to ingredients directly from the soil, treated without artifice.” Albala notes that an appreciation of food close to its natural state is at least an indirect consequence of Daoism.

Fried (2004) shows how failing to follow the appropriate eating etiquette and form led to disastrous results in Zhang Yimou’s 1992 film *Raise the Red Lantern*. Traditional sayings emphasized the centrality and importance of food in China, for example, “To the people, food is Heaven.” In this film, Master Chen takes a fourth wife or concubine, and the new wife contravenes the expected food etiquette in various ways thus committing serious ethical and social breaches which – with some other factors – lead to a disastrous outcome for her. Thus the movie demonstrates that “communal adherence to food etiquette and the rituals of dinner reflect societal behavior critical for all aspects of household and societal harmony; if dinner is disrupted, so is the flow of daily life” (Fried 2004: 131).

Even though Confucian beliefs, such as those underlying the above example, and Daoism were passed on to Korea and thence to Japan, the impact of Buddhism on ethical beliefs and norms relating to food is perhaps more directly important in China than Confucianism or Daoism. From its origins in India, Buddhism made such rapid inroads into China that Morris (2010: 323) refers to “Buddhism’s conquest of China.” From a few hundred adherents in 65 CE, Buddhism claimed perhaps 30 million followers by the sixth century.

In understanding the impact of Buddhism on ethical beliefs about food and eating in China, it is essential to keep in mind that Buddhism is composed of multiple schools of thoughts and sects which have different consequences for ethical considerations about food. There are three broad schools of Buddhism and numerous sects within each. *Theravada*, or *Hinayama*, Buddhism is the oldest and considered the most conservative school, but it has few proscriptions on food. Most adherents live in Southeast Asia and Sri Lanka. *Vajrayana*, or *Tantric*, Buddhism originated in India and is most highly concentrated in India and Tibet. *Mahayana* is the largest of the three schools. It was highly influential in China and, in different varieties, in Korea and Japan.

The different schools of Buddhism and the differing interpretations within and between each have given rise to different approaches to the ethics of food. Monks and laypeople have varying obligations in regard to food. As Lapp (2013) notes, “the most prominent dietary practice, and question of ethical debate, pertaining to Buddhism has to do with vegetarianism.” This is related to the injunction not to do harm expressed in the doctrine of *ahimsa*. Practitioners are also called on to avoid eating the “Five Pungent Spices” – onions, garlic, scallions, chives, and leeks – because they may kindle sexual desire or anger.

Indianization, Sinicization, and Asian Food Ethics

The food ethics associated with Hinduism and Buddhism also spread to Southeast Asia. Islam

also plays a key role. The impact of outside influences has waxed and waned in Southeast Asia, with both India and China notably influencing the area. Indianization, defined as “the influence of southern Indian traders and religious practitioners in Southeast Asia” (Van Esterik 2008: 5), brought Hinduism, Buddhism, and mixtures of both to the region. Theravada Buddhism is mainly practiced in mainland Southeast Asian countries, including Myanmar, Thailand, the Lao People’s Democratic Republic, and Cambodia, although practices vary among them. In terms of ethics and food, “Buddhism and food intertwine at the level of rituals and lay offerings, but also at the level of ideology and text” (Van Esterik 2008: 99). There is an emphasis on moderation in food or what could be called “moderate asceticism” (Van Esterik 2008). Theravada Buddhists are not generally vegetarian and neither are most Southeast Asian societies.

Van Esterik points out that where Mahayana Buddhism is more popular, such as in Vietnam, vegetarianism is more widely spread. Vietnam is the most Sinicized country in Southeast Asia. China had numerous influences in Vietnam, but one is the use of chopsticks. Vietnam is the only Southeast Asian society in which this is the case (Van Esterik 2008).

Korea’s closeness to and interaction with China ensured that both Buddhism and Confucianism would spread to Korea. By the fourth-century BCE, both belief systems were present in Korea, and both influenced numerous aspects of Korean culture, including cuisine. The Buddhist Koryŏ Dynasty (918–1392) unified the Korean peninsula, and the succeeding Chosŏn Dynasty (1392–1910) was guided by Confucian beliefs (Pettid 2008). In terms of the ethical aspects of Korean food, the type of Mahayana Buddhism that developed in Korea led to the popularity of vegetables of all sorts and to the development of various vegetarian dishes. This was not completely new. “The tradition of incorporating numerous vegetables and greens into foods probably is an ancient one that evolved from pre-agrarian times and was greatly enhanced by Buddhist beliefs that one should refrain from eating meat” (Pettid 2008: 51).

As in China, Confucianism had less to say about what to eat but emphasized how to eat and in what order. There was an order to who would eat first and in what order people would eat, especially in better-off families. Pettid notes these patterns “reflect the Confucian view of the hierarchy governing gender and age relations” (2008:159).

Buddhism and Confucianism also entered Japan from at least the sixth-century BCE, and both have been extremely influential there, especially Buddhism. There are numerous sects with varying foci. In terms of food ethics, one of the most influential thinkers was the Buddhist monk Dōgen (1200–1253). He founded the Soto Zen sect and wrote a manual on cooking. *Shōjin ryōri* cuisine, which is Buddhist vegetarian cuisine, emerged from the ideas of Dōgen and others (Ashkenazi and Jacob 2000).

Contemporary Ethical Issues

In introducing this work, the editors point to expanding areas of interest within the study of food and agricultural ethics. “These wide-ranging debates encompass questions in human nutrition, animal rights and the environmental impacts of aquaculture and agricultural production” (Thompson and Kaplan 2013). Among these and other topics, the continuation of what Carolan (2012) refers to as the “globalizations” of food takes on exceptional significance, as does a dietary transition that transforms food around the world (Smil and Kobayashi 2012). This transition is eroding some of the distinctiveness of food around the world, lessening culinary differences, and raising questions about health and well-being. As diets around the world, including in Asia, trend to more Western diets with heavier consumption of meat, diabetes and other diseases become more common. The appeal of meat also raises questions of sustainability, with some scholars arguing that meat eating is essentially not sustainable (McWilliams 2012).

The importance of the ethical dimensions of food and agriculture is also evident in the decision of the Food and Agriculture Organization (FAO) of the United Nations to publish their Ethics Series.

The foreword to the first entry in the Ethics Series of the Food and Agriculture Organization (FAO) of the United Nations starts by commenting that “the stubborn persistence of hunger and poverty raises what are perhaps the most burning ethical questions of our age (FAO 2001: iii).” The importance of food ethics has become increasingly clear in recent years, as indicated, in part, by this encyclopedia as well as the FAO series.

As the FAO indicates, the most basic ethical issue remains access to food. Over one billion people do not get enough food, while almost one and one half billion are overweight. These extremes are linked and they affect many in Asia. The debate over food security – the ability of people to get nutritious affordable food through regular channels – has become a major issue all over the world, with India being a powerful example. The Food Security Ordinance of 2013 addresses food security issues, in some ways helpfully, but in others not. According to development economist Jean Drèze (2013), “the food security bill is a fraction of what is required to tackle India’s enormous nutrition problems.” The issue of food security leads to questions of what is the ethical imperative of the developed world to ensure adequate food and nutrition in the developing world and in the pockets of food insecurity in developed societies.

Other ethical considerations arise in regard to topics such as the Green Revolution and Genetically Modified Organisms (GMOs) and attempts by corporations to patent foods and processes developed by cultivators in many parts of the world, including Asia. Contemporary Asia, and the rest of the world, faces many challenges related to the food system, many of which have ethical dimensions or straddle the elusive line between ethics and politics. However, the most compelling is that of hunger or food security.

Summary

This piece introduced the topic, spelling out its limitations and scope in terms of Asia, cuisine, and ethics. After examining the origins of food, it moved to consider the ethical aspects of food in

India and then China, emphasizing the belief systems and religions that generated ethical beliefs on food. It then looked at the spread of those belief systems and food ethics to areas in Southeast and East Asia. The piece concluded with an overview of contemporary ethical issues relevant to food in Asia.

[Authentic dishes](#); [Dishes](#); [Traditional foods](#)

Introduction

In reference to dishes, authenticity is a central axiological category, informed by aesthetic and ethical concerns, much used and abused on the part of both consumers and retailers. The application of the concept of authenticity to dishes has indeed grown to be so widespread that – in contrast with a previous reading of the term – some scholars regard judgments of authenticity as social constructs far from any possibility of falsification. Another school of thought, instead, sees authenticity as the expression of a genuine existential sentiment. In order to present the different perspectives, the entry opens up with some terminological remarks on the use of the expressions “dish” and “recipe.” To be offered next is an examination of different interpretations of “authenticity,” then employed to present four perspectives on the authenticity of a dish.

Dishes and Recipes

Before proceeding any further, the reader shall be made aware of certain important disambiguations. “Food” is sometimes used to refer to a *dish* and other times to a *recipe*, two notions whose difference shall be explained below. For the sake of clarity, the use of the expression “food” will be limited in the remaining of the entry, specifying which of the two senses is intended. Secondly, “food,” “dish,” and “recipe” are subject to a similar double interpretation: at times they refer *merely* to the item that is consumed – say, a tray of tiramisu; in other contexts, however, the expressions refer to that item *plus* the relevant events that brought to its realization; the relevant events, in turn, may be limited to the action of the cook (say, all the toil and labor that went into preparing the tiramisu) or rather include a more extended series of events (e.g., the chicken farm where the eggs were produced). The latter will be termed the *extended food/dish/recipe concept*. This entry will mainly attempt to offer a characterization of dishes and recipes in the extended sense; a derivative understanding of the less extended versions may ensue.

Authenticity, in reference to foods, is more aptly predicated of dishes; an authentic dish is a dish authentically reproducing a recipe. It is, then, relevant to explain the distinction between dishes and recipes. To put it bluntly, a dish is the *stuff*, a recipe is the *idea*. More precisely, a dish is the specific concoction of that perishable edible stuff, such as *those* specific actions that led to *this* tray of tiramisu sitting on my kitchen counter. On the other hand, a recipe is – in first approximation – the array of repeatable aspects that are found within a dish; that is, a recipe comprises any relevant aspect of a dish whose replication would deliver a dish of the same sort. In this sense, recipes stand for those *sorts* of actions that deliver certain *sorts* of dishes.

What is the relationship between recipes and dishes? Utilizing a terminology familiar to the contemporary literature in metaphysics, a dish can be an *instance* of a recipe or, alternatively, an *example* of a recipe. This tray of tiramisu – a dish – is an instance of tiramisu’s recipe; last week another instance of tiramisu was prepared, which has now been all eaten up.

Not every dish, however, need exemplify some recipe. While in principle every dish has some aspect to it that could be replicated, only selected dishes enter the ranks of recipes. Indeed, it might be that some dishes are such gerrymandered or random concoctions of foods that there is no relevant repeatable aspect to them. Furthermore, a recipe may exist before having been instantiated or, in extreme cases, without ever being instantiated. Before executing a novel recipe for the first time, it seems accurate to say that the chef who came up with it had the recipe. Other times, of course, the dish and the recipe come to be simultaneously: as the chef makes a dish, she is also – maybe accidentally – discovering the recipe.

Even if for every dish there is a recipe, the partition of dishes into recipes would still remain the most salient matter of dispute in the foodworld. Do *cecina* and *farinata*, as found respectively in the Italian culinary *milieus* of coastal Tuscany and Liguria, indicate different recipes? Who is entitled to judge of the matter? The partitioning of the foodworld, whose study lies beyond the scope of the present entry, is thus

crucial to establish the identity of both dishes and recipes.

“Authenticity”

The axiological relevance of authenticity can hardly be overestimated. Its underpinnings may concern either the aesthetic value of a situation or a thing, or its ethical worth, or both, depending on the context in which the term is employed and on the rationale for its usage. The expression “authenticity” has indeed much relevance in a number of fields, including visual arts, musicology, and cuisine. In reference to a person, authenticity stands for a virtuous disposition, achieved through the cultivation of simpler traits such as discernment, honesty, sound reasoning. In philosophy, the idea of an authentic life occupies a central role in existentialist philosophy and has been employed most notably by figures such as Kierkegaard, Nietzsche, Heidegger, and Sartre (cfr. Ferrara 1998; Taylor 1992). Being an authentic person means being *true to yourself*. In a nutshell, regardless of external conditions, the authentic person will persist in her most fundamental propositions. However, it is key not to confuse authenticity with stubbornness. The stubborn will persist in her decisions even when they contrast with paramount changes not just in external conditions but also in personal convictions; the authentic person, instead, will be able to discern her changes and channel her actions in such a direction that they will be most suitable in keeping with her present dispositions and, when applicable, her history. Personal authenticity, then, is entrenched with creativity. The truth in question, when it comes to the authentic life, is uncovered through a creative process rather than via an examination of the past or a measurement of what is present.

How authenticity applies to the arts is much debated. To address the issue, it is useful to borrow the distinction, introduced by Nelson Goodman (1976), between *allographic* and *autographic* forms of art. The former can be represented by a language other than the one in which they are expressed; an autographic piece of

art, on the contrary, cannot be expressed other than by itself. For instance, music is an allographic art because musical notation can make do for a musical piece – thus the limit case of pieces that have never be executed; on the contrary, painting is autographic, as any way of representing a painting cannot substitute for the actual work. In visual arts, where autographic works are predominant, authenticity seems to be employed especially to underline a genuine attribution of authorship; the opposite of an authentic work of visual art is, then, a *forged* work (cfr. Hick 2010). Central to an allographic form of art like music, instead, is the notion of *authentic execution* of a piece, and it is debated which performances best deserve such an etiquette (Kivy 1995) – those employing original instrumentation? Those eliciting similar effects in the audience? Those most faithfully interpreting the score, when available? Another story still is authenticity in the context of a collaborative art, as in the case of architecture, which is partially autographic and partially allographic. Three notions are most relevant in architecture: authenticity as authorship, as opposed to forgery; authenticity as cohesion, on the part of an architect, with her own past projects; or authenticity as adequate application of certain architectural creeds to a given situation.

Dishes are human artifacts bearing aesthetic worth; although it is debated whether selected foods may be regarded as forms of fine art (cfr. Telfer 1996, chapter 3), what said of the arts has a bearing on foods as well. First, we may wonder whether cuisine is an allographic or autographic endeavor. There are several means of expressing a recipe, from cookbooks to culinary reports to videos: this suggests the allographic nature of cuisine. On the other hand, none of the means to express a recipe seems to be able to fully substitute for the actual execution of a recipe that is a dish; the upshot is that cuisine has a fundamental component of creativity too, an adaptation of a generic procedure to circumstances. The unavoidable creative component is implied also by the fleeting nature of food. Out of material necessity, each dish employs novel ingredients: food is perishable and transient; taste is a *destructive* sense, as it destroys what it experiences; and cuisine is a

destructive endeavor, as it irreversibly transforms what it prepares to be consumed. Thus, whoever creates a dish, even on the score of a recipe, will be employing ingredients that are *unique* and that contribute crucially to the aesthetic quality of the gastronomic experience.

Authenticity in Foods

The authenticity of foods has been at the center of a wide debate in the social sciences, particularly intense in the last 15 years, so much so that, according to Taylor (2001, p. 8), “there are at least as many definitions of authenticity as there are those who write about it.” In the attempt to devise some threads in the literature, we may extrapolate four distinct perspectives:

1. *Realist perspectives on the authenticity of a dish.* The realist maintains that judgments of authenticity are true or false depending on whether the dishes have or lack certain characteristics. For instance, from a reading of Boorstin (1964), one may extrapolate the idea that an authentic dish reenacts a recipe in accordance to a specific relationship between a people and a place. Boorstin’s proposal, however, has been criticized because it presumes a *static* view of a culinary culture, as opposed to one accommodating the seemingly unavoidable possibility of its evolution. Realist perspectives on the authenticity of a dish need not be static, however. It is possible to recognize that certain traits are essential, *at a given time*, in establishing the authenticity of a dish, without assuming that such traits will be valid in the future. Geographical indications (cfr. entry on GIs), which will be more fully considered below, are a case in point here. While the geographical area of production and the essential features of a product such as Champagne wines have changed over the centuries, current standards of production provide allegedly objective criteria on the basis of which a wine is judged as an authentic champagne. Of course, some may argue that the standards associated to a geographical indication are
2. *Constructivist perspectives on the authenticity of a dish.* Constructivist perspectives on the authenticity of a dish move from the observation that no human culture is ever wholly separated from all other cultures; rather, cultural contamination is the norm. What comes to be seen as authentic, then, is the outcome of a selection process ultimately guided by human *fiat*. For instance, there is no objective boundary between authentic and non-authentic Thai cuisine, rather some ingredients, cooking methods, serving tools, etc. are chosen by consumers as being more authentic than others (cfr. Germann Molz 2004; Urry 2005). Analogous considerations will be made with respect to geographical indications: the borders of the Chianti Classico region as well as the rules and regulations regimenting its production are not discovered, but conventionally established. The upshot – as summed up by Sims (2009) who draws on Jackson (1999) – is that “instead of talking about “authenticity,” we should focus upon “authentification,” which is the process whereby people make claims for authenticity and the interests that those claims serve” (Sims 2009, p. 324).
3. *“Existentialist” perspectives on the authenticity of a dish.* Some existentialist notions have entered the contemporary debate on tourism and authenticity (cfr. Wang 1999; Sims 2009, pp. 324–325); the ensuing proposal may be labeled “existentialist,” among quotes, since it comes free of the broader theoretical framework of existentialism. The basic idea – when applied to our case in point – is that gastronomic experiences contribute to create a sense of the self; the quest for authentic dishes, then, becomes the quest for the realization of an authentic self. This perspective shares much with the constructivist, as it starts from the assumption that there can be no objective authenticity of a dish; on the other hand, for the “existentialist,” there is a form of

authenticity which may be genuinely devised – personal authenticity. What sorts of experiences are conducive to personal authenticity and which ones are not, however, remains to be cleared. We may speculate that those experiences conducted independently from societal constraints and in keeping with core personal creeds are to be preferred; still, work remains to be done in this area.

4. *Naïve perspectives on the authenticity of a dish.* Finally, we come to a perspective paying dues to naïve approaches to authenticity (Cohen 2002). To an ordinary gastronome, some dishes *are* authentic, without the need to justify why that is the case. What to a culture theorist appears as a social construction or an “existentialist” quest to the naïve gastronome is simply a *sui generis* experience: it is all a matter of relaxing and enjoying a certain way of preparing and serving food. At times, there, you will encounter authenticity.

Authenticity in a Globalized World

The naïve perspective on authentic dishes opens the door to some conclusive remarks on the importance that the concept of authenticity in the kitchen has assumed in contemporary society. Three are the domains where the concept is more notably employed. The first comprises all experiences of “exotic eating” in local restaurants (Heldke 2003), as when visiting a Thai restaurant in Helsinki or an Italian restaurant in Bangkok. Such contexts typically reinforce the conviction that a realist perspective on authentic dishes is of little use.

The second domain is tourism (Heldke 2005; Sims 2009). Also in this context, we find chief examples reinforcing the thesis that the realist perspective is untenable. In tourism, indeed, the traveler’s demand for an authentic experience encounters the needs of merchants to package an experience that will match the expectations. Thus, landscapes will be “beautified” so to appeal to visitors – for instance, in a region famous for its wines, vineyards will be embellished and become predominant with respect to other plants;

restaurants will orient their menus on the basis of the preferences of the visiting clientele; and architectural styles and internal décor of living spaces will seek to match the tourist image of a place.

The third domain is the quest for local foods, particularly important to study as it suggests that the realist perspective held strong up to these days. Authenticity is indeed often associated to local foods and geographical indications, which in the mind of most consumers demarcate genuine, real relations between foods and places, making for an unrepeatable experience. Here is an example attesting the trend, from a study by Sims of two regions within the United Kingdom, the Exmoor, and the Lake District:

Tourists tended to associate local food with particular specialty products. Of the 36 Exmoor tourists interviewed, 32 were able to name specific examples of foods and drinks that they associated with the area, with a similar trend being observed in the Lake District, where 38 of the 42 tourists identified at least one food or drink product with the area. (Sims 2009, p. 330)

The variety of contexts within which authenticity has come to play a role in food discourse suggests that more than one of the four perspectives presented above may come in handy to analyze a specific case. As taste and culinary cultures evolve, more work remains to be done in ascertaining the nuances of each perspective.

Summary

Some terminological remarks on the use of the expressions “dish” and “recipe” are offered first. Follows an examination of how the concept of authenticity has been employed in philosophy both to describe a personal quest (in connection especially with existentialist philosophies) and to characterize a work of art. Next, four perspectives on the authenticity of a dish are presented: realist, constructivist, existentialist, and naïve. The conclusive section, which points out three domains where the concept of authentic food is of particular significance, suggests that depending on the case study at hand, different perspectives turn out to be most suitable.

Introduction

The ethics of food animal production did not represent a significant area of societal concern until 25 years ago, with the rise of public attention to both environmental consequences of raising food animals and effects of production systems on animal welfare. Beginning with Jeremy Rifkin's *Beyond Beef: The Rise and Fall of the Cattle Culture* (Rifkin 1993) and continuing with other books such as Michael Pollan's *The Omnivore's Dilemma* (Pollan 2006) and the UN report of 2006 *Livestock's Long Shadow* (UN 2006) and films such as *Food, Inc.* (2008) and periodic reports linking meat to the epidemiology of various diseases, ranging from cancer to

cardiovascular diseases and bird flu, public scrutiny of meat industries has increased exponentially and led to campaigns in favor of limiting meat consumption, such as *Meatless Mondays*. In particular, beef has been hit hard, as fear of red meat has proliferated. Consider, for example, the pork industry's position absurdly calling pork "the other white meat."

Probably the most accurate document on the ethical issues occasioned by meat production is the report of a 3-year study by the Pew Commission on Industrial Farm Animal Production, published in 2008 as *Putting Meat On the Table: Industrial Farm Animal Production In America* (Pew 2008; available online at PCIFAP.org). The commission consisted of 14 experts on various aspects of animal production, who spent more than 2 years studying all of the major meat production systems dominating the US landscape. The commission focused on a variety of ethical issues arising out of such systems, including environmental despoliation, animal welfare, human health, rural communities, worker health and welfare, animal health, animal welfare, and food safety. All commission recommendations published required unanimous agreement from all commissioners. The report was the first systematic account of the problems raised by confinement agriculture since its inception and was well received and well reviewed. One industry expert revealingly called it "a blueprint for the future of animal agriculture in America."

Historical Considerations

Current thought places the domestication of cattle at somewhere between 7,000 and 9,000 years ago. So important was this event to human history that veterinarian–historian Calvin Schwabe calls the cow "the mother of the human race" (Schwabe 1978). Cattle were utilized historically for food, leather, transportation, haulage, plowing, and their dung used for fuel.

In the United States, the production of beef has changed comparatively little in comparison to the production of other animals, with only sheep production undergoing similar minor modification.

Cattle production today can be divided into extensive ranching, or cow-calf production, and more intensive cattle feeding, based on utilizing grain to produce fat cattle. Ranching is without a doubt the most unchanged among animal production systems in many hundreds of years. Typically, cattle are grazed in large open areas of pasture or native indigenous grasses. A minority of producers will grow the animals to market weight on such forage. Beef from such animals is designated as "grass-fed" meat and is more commonly produced in South America, where there are vast areas of grassy forage. After World War II, when the improvements in crop production known as "the Green Revolution" produced huge increases in available grain, the practice of feeding grain to cattle in order to increase profitability began, since the grain is worth considerably more when it creates meat in animals than when it is marketed strictly as grain. Eventually, the US public developed a preference for "grain-fed" beef until gradually the meat from such cattle dominated the market, and "grass-fed beef," which is generally not as tender as beef from cattle fed grain, became a specialty item rather than a staple of consumer diets.

Environmental Issues

From an environmental perspective, grass-fed beef fattened on indigenous forage is a good deal more sustainable than grain-fed beef. After all, there are significant energy costs involved in transporting grain to the animals, keeping the animals highly concentrated in feed yards, disposing of the manure, which creates odor and ground-water contamination. In addition, a great deal of energy is expended shipping cattle to feedlots and from feedlots to processing plants and markets. It is clear that fattening and marketing beef locally has a far smaller environmental impact than moving animals and meat across the country.

Estimates of the amount of water required for producing 1 lb of beef range from a low of 441 gal to a high of 2,500. These estimates clearly vary with the political bias of the source. The higher figure comes from a vegetarian website (Vegsource 2001), the lower from an industry

website (Explore Beef 2012). There is, however, no question that the production of beef does utilize a good deal of water. Similarly, there are predictably huge variations in estimates of greenhouse gas production created by the cattle industry. (It is important to stress that claims regarding anthropogenic causes of global climate change are greatly disputed in the scientific community.) The largest environmental impact from beef occurs in South America, where “slash-and-burn” techniques for clearing the rainforest to produce grazing land for cattle result in impoverishing the rainforest environment and potential desertification. It is therefore clear that the production of beef does have some impact on the environment. The issue is how significant is that impact, and can it be mitigated. It is also argued that the production of beef by grazing preserves a significant amount of land, with 85% of that land in the United States unsuitable for any use other than grazing. Since Western ranch lands are among the most beautiful landscapes in the United States, it has been suggested that ranching helps preserve land that would otherwise fall prey to development. Coalitions between environmentalists and ranchers developed in the 1990s have pressed “cows not condos” as a rather surprising common interest. Ranchers sometimes feed deer and elk over difficult winters.

Human and Animal Health Issues

Shortly after the discovery of antibiotics in the 1940s, it was noted that regular feeding of such drugs was conducive to growth promotion in farm animals. Although the precise mechanism by which this occurs remains unknown, various explanations have been suggested, including the claim that these drugs reduce subclinical infections which cause animals to utilize energy to fight disease-causing organisms rather than utilizing that energy to promote growth. In 1985, a Swedish referendum banned the use of antibiotics for growth promotion. After a frantic search for alternatives, it was suggested that significantly increasing cleanliness and hygiene in animal facilities could reduce pathogen load and thus eliminate the traditional use of

antibiotics. Such an effort was introduced, and subsequently the cost of animal products fell, showing that in modern animal factories in which animals are severely crowded and antibiotics are deployed as a way of covering up the effects of pathogenic, unhygienic conditions, a remedy is increased sanitation. In other words, antibiotics were utilized as “technological sanders” so that “square pegs” could be forced into “round holes.” In general, in such cases, it makes more sense to improve the animals’ living conditions, rather than attempting to cover up the effects of less than optimal husbandry (Rollin 2001).

Very early in the history of antibiotic use for growth promotion, it was suggested on the basis of simple Darwinian evolutionary principles that such use would inevitably drive bacterial resistance to antibiotics. The mechanism creating such resistance is conceptually simple. As greater amounts of antibiotics are fed to farm animals, resistant pathogens are killed off, creating new opportunities for nonresistant pathogens to colonize the ecological niche in question, thereby in effect breeding for drug-resistant pathogens. That this in fact occurred has been demonstrated empirically.

Whereas much of Europe has followed the Swedish lead and banned nontherapeutic use of antibiotics, the United States has been considerably less proactive. Although regulatory agencies such as the Centers for Disease Control have strongly agitated for such policy, agricultural lobbyists have blocked massive policy change. Though the largest amount of antibiotics is utilized in the beef industry, these drugs are not typically cutting-edge antibiotics that represent the final line of defense against certain bacteria. The chicken industry, on the other hand, keeps animals under such pathogenic conditions that antibiotic residues from cutting-edge drugs utilized against dangerous human pathogens, such as fluoroquinolones, have been found in ground-water near poultry facilities, as well as in chicken meat purchased in groceries.

It is clear that use of antibiotics in beef cattle increases production efficiency. It has been claimed, for example, by the Animal Health Institute, a meat industry lobby group, that to reach

current beef production levels without antibiotics would require 23 million additional cattle. Despite growing political pressure to ban antibiotic use for growth promotion in cattle and other farm animals, the US Congress has failed to act, and thus the United States is well behind Europe on such limitation of antibiotic use. This author served on a World Health Organization panel setting guidelines for prudent use of antimicrobials in 2000. At this conference, there was significant public pressure to ban *any* antibiotic use in farm animals to protect humans. This proposal was defeated on ethical grounds, as it was argued that we have a moral obligation to treat patently sick animals being raised under our aegis.

The issue of antibiotic resistance appears almost exclusively in cattle fattened in feedlots, not in animals that are ranch-raised under extensive conditions, and generally not fed antibiotics. There are other health issues, human and animal, that emerge in the course of the production of beef. Animals are significantly more crowded in large feedlots, which may contain up to one million animals in a relatively small space, than they are under range conditions. Furthermore, the animals in feedlots and processing plants come from many different locations and thus would harbor more diverse pathogens than would animals on pasture. The bulk of dangerous microbes are found in fecal material and are more easily spread in confinement, though pathogens from range cattle feces may cause problems by leaching into groundwater. Antibiotics such as chloramphenicol, which have been shown to leave residue in meat, may cause human health hazards beyond accelerating antibiotic resistance. Chloramphenicol, for example, when consumed in meat, can lead to aplastic anemia and was thus banned for use in cattle (Rollin 2001).

In recent years, transfer of dangerous pathogens onto carcasses has been illustrated by the case of *E. coli* O157: H7, an enteric bacterium found in cattle and capable of causing severe, even fatal intestinal disease in humans, particularly in children. An outbreak of such cases led the beef industry to increase cleanliness and avoid carcass contamination in packing houses by decontaminating them during processing, a prophylactic procedure that seems to have reduced

the threat to public health. In general, the beef industry seems to be the most proactive of all meat production industries as regards risks to human health, though it would probably be wise to “cowboy up” and eliminate antibiotic use for anything other than treating patently sick animals.

Additional risks associated with the consumption of beef are “mad cow disease,” or bovine spongiform encephalopathy (BSE), a fatal neurological disease caused by *prions*, and longstanding accusations leveled against beef regarding cardiovascular disease arising in some people from unsaturated fat and cholesterol. Risk of BSE in the United States is virtually nil. Responsibility for cardiovascular problems seems to fall upon the individual consumer and his or her choice of the amount and sort of beef consumed, rather than on the industry.

Animal Welfare: The Transformation of Animal Agriculture from Husbandry to Industry

The traditional account of the growth of human civilization out of a hunter-gatherer society invariably invokes the rise of agriculture, i.e., the domestication of animals and the cultivation of crops (Rollin 1995, 2004). This of course allowed for as predictable a food supply as humans could create in the vagaries of the natural world – floods, droughts, hurricanes, typhoons, extremes of heat and cold, fires, etc. Indeed, the use of animals enabled the development of successful crop agriculture, with the animals providing labor and locomotion, as well as food and fiber. The “ancient contract” with animals, was a highly symbiotic relationship that endured essentially unchanged for thousands of years. Humans selected among animals congenial to human management and further shaped them in terms of temperament and production traits by breeding and artificial selection. The animals provided food and fiber – meat, milk, wool, leather – power to haul and plow, and transportation and served as weaponry – horses and elephants. As people grew more effective at breeding and managing the animals, productivity was increased.

As humans benefited, so simultaneously did the animals. They were provided with the necessities of life in a predictable way. And thus was born the concept of husbandry, the remarkable practice and articulation of the symbiotic contract. The essence of husbandry was care. Humans put animals into the most ideal environment possible for the animals to survive and thrive, the environment for which they had evolved and been selected. In addition, humans provided them with sustenance, water, shelter, protection from predation, such medical attention as was available, help in birthing, food during famine, water during drought, safe surroundings, and comfortable appointments.

Eventually, what was born of necessity and common sense became articulated in terms of a moral obligation inextricably bound up with self-interest. In the Noah story, we learn that even as God preserves humans, humans preserve animals. The ethic of husbandry is in fact taught throughout the Bible; the animals must rest on the Sabbath even as we do; one is not to seethe a calf in its mother's milk (so we do not grow insensitive to animals' needs and natures); we can violate the Sabbath to save an animal. Proverbs tells us that "the wise man cares for his animals."

The true power of the husbandry ethic is best expressed in the 23rd Psalm. There, in searching for an apt metaphor for God's ideal relationship to humans, the Psalmist invokes the good shepherd:

The Lord is My shepherd; I shall not want.
He maketh me to lie down in green pastures,
He leadeth me beside the still waters,
He restoreth my soul.
We want no more from God than what the good shepherd provides to his animals.

Though this ancient contract with domestic animals was inherently sustainable, it was not in fact sustained with the coming of industrialization. Husbandry was born of necessity, and as soon as necessity vanished, the contract was broken. The industrial revolution portended the end of husbandry, for humans no longer needed to respect their animals to assure productivity.

Animal husbandry may be characterized as putting square pegs in square holes, round pegs in round holes, and creating as little friction as

possible in doing so. Failure at husbandry meant that one's animals did not produce; failure to respect animal needs and natures hurt oneself as well as the animals. This was suddenly overridden by technological tools, as it were "technological sanders," that allowed people to force square pegs into round holes and round pegs into square holes, and where, at least in the short run, productivity flourished at the expense of respect for animal needs and natures. These tools replacing the need for husbandry included antibiotics, vaccines, bacterins, air handling systems, and manure handling systems and resulted in systems that do not respect the animals' physical and psychological needs and natures (Rollin 1995, 2004).

The singular beauty of husbandry is that it was at once an ethical and prudential doctrine. It was prudential in that failure to observe husbandry inexorably led to ruination of the person keeping animals. Not feeding, not watering, not protecting from predators, not respecting the animals' physical, biological, psychological, and physiological needs and natures – what Aristotle called their *telos*: the "cowness of the cow," the "sheepness of the sheep" – meant your animals did not survive and thrive, and thus neither did you. Failure to know and respect the animal's needs and natures had the same effect. The ultimate sanction of failing at husbandry – erosion of self-interest – obviated the need for any detailed ethical exposition of moral rules for husbandry: Anyone unmoved by self-interest is unlikely to be moved by moral or legal injunctions! And thus one finds little written about animal ethics and little codification of that ethic in law before the twentieth century, with the bulk of what is articulated aimed at identifying overt, deliberate, sadistic cruelty, hurting an animal for no purpose or for perverse pleasure, or not providing food or water.

Animal Welfare in Modern Industrial Agriculture: The Beef Industry as Preserving Animal Husbandry

Even the superficial examination of modern agricultural systems reveals the almost total loss of animal husbandry and its replacement by

industrial approaches, and “technological fixes.” Whereas, historically, the dairy industry represented the paradigm of good husbandry, with quantitatively and qualitatively high milk production, it was solidly dependent on good animal husbandry. Cows lived on pasture, to which they were well adapted. Herds of milk cows were small, and dairy farmers knew each cow as an individual, and often by name. Though lameness was not unknown, it did not pose the huge problem it does today, due to the fact that the animals often live in herds of 10,000 or more and largely are maintained on concrete, footing totally unsuited to cow hooves. Whereas yesterday’s dairy cow could remain productive for 20 years, today’s cow lasts barely 2.5 lactations. While milk production has skyrocketed, cow welfare is greatly compromised. Mastitis is rife, as are foot and leg problems.

A similar dark picture can be painted regarding animal welfare in virtually all confinement animal production systems. Modern veal production systems grew out of the dairy industry and were probably the first industry to shock the public when the media showed calves raised in isolation in dark small wooden crates and kept marginally anemic to assure pale, soft flesh. These miserable animals could not even walk to the trucks by which they were transported to slaughter. Laying hens are kept in small cages, as many as 9 per cage, and never see the light of day and debeaked to avoid cannibalism. Broiler chickens are raised in dark barns, where the air quality is appalling in terms of ammonia levels. (When the Pew Commission toured an “exemplary” barn chosen by the industry, a number of commissioners developed asthma symptoms after a few minutes.) Confinement swine operations are equally horrendous. Mother pigs are kept confined in 2’ by 7’ by 3’ “gestation crates,” in which these animals cannot stand up or turn around or, in the case of large sows, must lie in an arched posture. The animals again never see the light of day, lie on concrete slats in their own excrement, and develop severe behavioral anomalies.

These systems typically inflict four kinds of suffering on the animals raised within them:

1. Production diseases arise from the new ways the animals are produced. For example, liver abscesses in cattle are a function of certain animals’ responses to the high-concentrate, low-roughage diet that characterizes feedlot production. Although a certain percentage of the animals get sick and die, the overall economic efficiency of feedlots is maximized by the provision of such a diet. The ideas of a method of production creating diseases that were “acceptable” would be anathema to a husbandry agriculturalist.
2. The huge scale of industrialized agricultural operations and the small profit margin per animal militate against the sort of individual attention that typified much of traditional agriculture.
3. Another new source of suffering in industrialized agriculture results from physical and psychological deprivation for animals in confinement: lack of space, lack of companionship for social animals, inability to move freely, boredom, austerity of environments, and so on. Since the animals evolved for adaptation to extensive environments but are now placed in truncated environments, such deprivation is inevitable.
4. In confinement systems, workers may not be “animal smart”; the “intelligence,” such as it is, is in the mechanized system. Instead of husbandmen, workers in swine factories are minimum wage, often animal-ignorant labor. So there is often no empathy with, or concern for, the animals.

Though the beef industry also employs confinement in feedlots, these systems are nowhere near as severe as the other industries. Generally, feedlot cattle are kept in large pens, where they can express much of their natural behavior. Welfare problems arise from historically poor drainage so that the animals may be standing in mud or frozen mud, since feedlots are typically sited in the Great Plains and Midwest. These areas are typically characterized by harsh winters, icy and severe winds, extremely hot summers, and lack of shelter and shade. The cattle, being ruminants, are built for grazing. But after the spectacular

increases in grain production after World War II, forage was replaced by grain. A certain percentage of the animals developed rumenal and liver abscesses, but the extra value added to the majority of cattle that did not more than offset the economic losses.

The quality of labor working in feedlots varies considerably regionally. In Colorado, both workers and managers tend to come from a cattle background and therefore are knowledgeable and often empathetic with the animals. Workers in feedlots in other states have quit in disgust at the callousness and lack of empathy of the employees they deal with. In one case, workers allowed sick animals to freeze in a puddle!

Generally, feedlots have improved over the past couple of decades. Most noteworthy, perhaps, is that the stocking density has been considerably diminished, and drainage has been considerably improved. When members of the Pew Commission toured a very large Colorado feedlot after touring dairies, swine facilities, egg “farms,” and broiler operations, they were pleasantly surprised at the lack of obvious welfare problems and the condition of the animals. But there is certainly no assurance that all feedlots conform to even a minimum welfare standard (Pew 2008).

Transport from feedlots to packing houses can create welfare issues during extremes of temperature. High stress can result in “shipping fever,” which can be reduced by “preconditioning” cattle. Bruising represents an additional welfare issue.

Western Ranching: Cow-Calf Operations

As mentioned earlier, extensive ranches represent the last and best examples of the husbandry ethic in today’s agricultural world. The vast majority of ranches are small (with some notable exceptions) and family owned and operated. The primary value driving ranchers is way of life – how they interact with animals, nature, and the environment. Despite the fact that many Americans see ranchers as plutocratic land barons as was depicted in the movie *Giant*, driving Rolls-Royce pickups, this is far from the case. About 10 years ago an animal scientist reported that the

average income of a rancher living in the Front Range (Eastern slope of the Rocky Mountains) was \$35,000. And a huge part of ranchers’ ethic is care for the livestock. The vast majority of ranchers would affirm, “if I had to raise animals the way the chicken or pig people do, I would get the hell out of the business.” Unlike these other industrialized, confinement industries, the animals live their lives extensively, as their natures dictate. There are few “technological sanders” deployed in ranching because there is no forcing of square pegs into round holes. Structurally, there is very little in ranching that forces compromising animal welfare. What is there are certain very invasive “management practices” such as castration without anesthesia and hot iron branding that are largely sanctified by custom and tradition.

This latter claim is supported by a thought experiment one can perform with rancher audiences: “if God came down and told you that you may continue to raise cattle, but you may not hurt them, would you go out of business?” Invariably, they say no. This of course evidences that these practices are dispensable or alterable to avoid pain.

Shortly after the birth of a calf, the same ranchers will brand, dehorn, castrate, and vaccinate these animals with no pain control in a festive, party-like occasion (Rollin 1995). How can this be reconciled with the ethic of animal husbandry, both historically and today? One can focus on branding for an in-depth look at such practices historically, conceptually, and ethically. Branding of cattle by the use of a hot iron to create an indelible mark on the skin by infliction of a third-degree burn can be traced back to the Egypt of 3000 BC. Obviously, such burns are extremely painful and work by destroying melanocytes or pigmentation cells. The purpose of the resulting mark in today’s world is twofold: first, it provides proof of ownership, with each ranch employing a unique, centrally registered mark. Second, it allows for easy recognition of one’s cows under mixed range conditions, where many different animals with numerous different owners may graze together. In addition, ranchers claim that brands help to prevent rustling, i.e., theft of cattle. With periodic change in cattle

ownership, an animal may be branded more than once.

Historically, there were no alternatives for permanently identifying cattle, nor were there methods for controlling the pain of the burn. Over the past 30 years, as industrial agriculture has become increasingly less acceptable to society, and a return to husbandry agriculture is sought, some ranchers realize that they would do well to underscore their commitment to animal welfare by eliminating painful management practices and marketing beef as the humane meat product. Ironically, the acceleration of modern technology that created confinement agriculture can also be utilized to replace painful management practices. One alternative to branding is provided by digitized retinal images of cow retinas, images with more data points than human fingerprints. Similarly, cattlemen could employ other biometric identifiers or electronic forms of identification such as microchips. All such methods provide permanent, unalterable forms of identification. These biometric and electronic forms of identification provide the additional advantage of facilitating trace back in the event of disease outbreak. In addition, branding does not prevent cattle theft. In many places, in remote areas, rustlers will drive to ranches with a truck, cut fences, slaughter cattle, and steal them as boxed beef. Inherently conservative, ranchers have resisted moving to alternative methods of identification. If asked to justify the infliction of a third-degree burn morally, cowboys will cite the trade-off involved in living extensively in exchange for a short-term burn pain.

Whereas, historically, few urban people had ever witnessed a branding party, this has changed dramatically with the advent of the Internet, and most people are horrified by it. On one occasion, a speaker at a large California ranch was approached by the wife of a meat buyer for a boutique supermarket chain. She closed the door and began to cry bitterly. She said she had just witnessed a branding, and that was the most horrific event she had ever seen, even though her husband's livelihood came from beef. "Those poor calves," she sobbed, "burned and terrified. It is horrible." Clearly, she thought of it as little

more than a sadistic pain ritual! Though sanctified by tradition, branding does not play well to urban audiences and does not win many friends for ranching, despite rancher commitment to husbandry!

Knife castration of beef cattle is another painful management practice originating in antiquity (Rollin 1995). Typically, neither anesthesia nor analgesia is utilized to control the attendant pain. Castration is done to reduce aggressiveness in male animals, thereby minimizing aggressive interactions and danger to humans, as well as to prevent unplanned impregnation of female animals and to improve the quality of the meat. Sometimes castration is accomplished by placing elastic or rubber bands around the testicles, creating ischemia so that the testicles eventually die and shrivel. As a prolonged insult, banding appears to be more painful than knife castration, although bloodless. Ways of mitigating knife castration include raising and marketing young bulls, which has been done successfully, use of local anesthetics and subsequent analgesics to mitigate pain, chemical castration, and immunological castration, which involves using the immune system to interfere with the spermatogenic cascade (Rollin 1995). Castration is particularly irrational economically, as the anabolic growth promotion of the testicles is often replaced by hormonal implants, which do not work as well as endogenous testosterone and which tend to be viewed with suspicion by consumers.

The difficulty of performing knife castration increases with the age of the animal. In Britain, it is permissible to castrate calves until 8 weeks of age without anesthesia. It is sometimes argued that newborn or young animals do not feel pain. This is extraordinarily implausible, given that calves are born precocious, i.e., "hit the ground running" in all biological systems. It defies belief that only the ability to feel pain conveniently does not exist until the animal is 2 months old. What is true is that as the animal gets older, greater vascularization is present, making control of bleeding more of a challenge than in younger animals.

Dehorning is utilized to prevent injury by horned cattle to each other and to humans. When

done to adult animals by cutting or gouging out the horns, the procedure is extremely painful and creates a bloody mess. When done on young calves, the so-called “disbudding” of the horn buttons can be accomplished less traumatically but still painfully by the use of caustic paste, electric irons, or cutting. Anesthetics and analgesics are virtually never used. A simple alternative to dehorning is to genetically introduce the poll or hornlessness gene into one’s herd (Rollin 1995).

There exist other mutilations that were historically more important than they are now. One was notching wattles of cattle for an additional form of identification. (Wattles are the loose skin hanging from the neck of cattle.) Unique patterns of notching were cut (again with no anesthesia) to represent various ranches to which cattle belonged. In a similar vein, but less invasive, were notches cut into the animals’ ears. (A similar form of identification is still used today with laboratory mice.)

A final mutilation brings chills to the average male when they learn of it. In cattle ranching, it is necessary to know when female animals are in heat. There are a variety of methods for heat detection, but one common method was to create surgically “gomer bulls.” Gomer bulls are normal males whose penis has been deflected and then surgically attached to the animal’s inner thigh. These animals, possessing the normal mating urge, will mount females who are in heat, but are unable to achieve penetration because of the unnatural position of the penis (Rollin 1995).

Summary

It should be evident from the discussion that the beef industry faces the smallest number of ethical issues of any modern animal production system, with small ranching the most pristine and most easily improved. Particularly in terms of sustainability, environmental despoliation, and animal welfare, the beef industry is the cleanest (Fraser and Broom 1990). For this reason, it is ironic that beef is often the whipping boy for well-intended but ignorant public criticism of the meat industry.

Introduction: Colony Collapse Disorder and the Disappearance of the Honey bee

In the last 3 months of 2006, beekeepers along the East Coast began seeing large disappearances of honey bee colonies. By the end of the year, the West Coast would experience these same losses. Since 2006, beekeepers have continued to experience substantial decline in their honey bee population. This phenomenon would be coined as colony collapse disorder and has continued to be a pressing issue. Honey bees (*Apis mellifera*) are responsible for pollinating one-third of the US diet and are said to be “the most economically valuable pollinators of agricultural crops worldwide” (Johnson 2010, p. 1). Having the annual monetary value of \$15–\$20 billion in the United States alone, the honey bee’s disappearance will have a large impact on how we live (Johnson 2010).

Before Colony Collapse Disorder

Although the disappearance of honey bees has become a popular topic in the media, honey bee loss is nothing new in the beekeeping industry. Over the past few decades, the number of honey bees has steadily decreased, dropping “61 % from their high of 5.9 million managed in 1947 to the low of 2.3 million reported in 2008...” (Peters 2012, p. 615). The slow decline of honey bees has been contributed to multiple factors, two of the main causes being arthropod pests and the pathogenic diseases they can spread.

Mite infestations have played a major role in the decline of US honey bee populations since the 1980s with the tracheal mite (*Acarapis woodi*) first being reported in 1984. The tracheal mite gets its name from living in the tracheal tubes of honey bees (Sammataro et al. 2000, p. 521). Infected bees show signs of weakness and shorter life spans (Sammataro et al. 2000, p. 521). Although the tracheal mite initially caused a substantial die-off in US colonies, honey bees soon became resistant to the mite. As this occurred, a new problem was introduced with the first varroa

mite infestation being reported in 1987 (Peters 2012).

Varroa mites (*Varroa destructor*) are another threat to honey bees. Also known as vampire mites, these parasites attach to the bodies of honey bees, living off their blood. Wounds left from the varroa mite leave bees weakened and susceptible to infection (Sammataro et al. 2000, p. 522). This varroa mite affects worker bees and male larvae as well as the queen’s reproductive abilities (Johnson 2010, p. 5). It is associated with viral pathogens and is linked to the disappearance of most feral bee in the 1990s (Johnson 2010, p. 5). An infestation of the varroa mite, if left untreated, “can kill a hive within six months to two years” (Peters 2012, p. 616). Symptoms include visible dark mites, bite marks, and deformed bees crawling in and outside of the hive (Sammataro et al. 2000, p. 522). The treatment of varroa mite involves the use of chemical pesticides, though beekeepers have found that varroa mites develop resistance relatively quickly, causing the control of these pests to be challenging. As a result, new pesticides have to be invented to solve this issue, costing money as well as labor.

Pathogenic diseases are easily spread by mites and are present in many colonies affected by CCD. The *Paenibacillus larvae* is considered one of the most dangerous of honey bee pathogens, causing American foulbrood (AFB) (Johnson 2010, p. 5). As the name suggests, American foulbrood affects larval honey bees. Once responsible for large colony losses, AFB incidences have been reduced with the use of antibiotics and increased hive inspections.

Since the 1990s, USDA colony losses averaged 17–20 % annually (Johnson 2010, p. 5). With the slow decline of honey bee populations, commercial beekeepers in the United States began having to import bees from countries such as Australia to pollinate California almond crops (Horn 2012, p. 63). The shipment of honey bees as a temporary solution to honey bee losses is thought to be inefficient as well as costly. The traveling itself is stressful to imported honey bees as well as the introduction to a new environment and weather (Horn 2012, p. 63).

Mad Bee Disease: France's Version of Colony Collapse Disorder

In the summer of 1994, French beekeepers began to notice their bees flying off and not returning, leaving only the queen and brood behind. Others began finding thousands of dead bees near their hives. With workers gone or dead, the queen bees and young eventually followed. Besides high mortality rates, honey bees also began to exhibit peculiar behaviors, including “trembling, keeping the tongue extended, excessive cleaning of the head and the antennae, etc.” (Peters 2012, p. 617). The bees also showed signs of apathy and immobility and were often “attacked by guard bees at the entrance of the hive” (Peters 2012, p. 617). The term “mad bee disease” was coined for France’s epidemic.

With large percentages of bee populations dying and disappearing, French beekeepers and scientists moved quickly to find the cause. One of the prime suspects in this case was Gaucho, a “neonicotinoid (chlorinated nicotine-based insecticide) containing the systemic pesticide imidacloprid” (Peters 2012, p. 617). In France, Gaucho was applied to sunflowers for the first time in the summer of 1994 when the bees began to disappear (Peters 2012, p. 617).

With Gaucho being the prime suspect for the large death and disappearance of the honey bees, French beekeepers requested further testing be done on the chemical. Bayer CropScience, the creator of Gaucho, conducted multiple tests on their products and after years of research reported that “the nectar sipped by bees did not contain lethal doses of the imidacloprid, therefore insisting their product was safe” (Peters 2012, p. 619). Bayer did not show the effects of sublethal doses, which could cause disorientation among the bees. Due to this disorientation, honey bees often lost their sense of direction and could not find their way back to their hive. Bayer also did not consider the “cumulative effect” Gaucho had on the bees that were exposed to imidacloprid through nectar, pollen, flowers, and leaves (Peters 2012, p. 619).

While Bayer claimed that their product was not responsible for mad bee disease, French

beekeepers continued to suffer “extreme losses.” By the end of the twenty-first century, 5 years after the first report of mad bee disease, “French production of sunflower honey had declined by more than fifty percent,” and by 2001, one-third of France’s honey bee population was lost to the disease (Peters 2012).

Though Bayer claimed that their product was not the cause of the catastrophic disappearance of bees, French beekeepers pressed for further research. After a year of testing, the French Agriculture Ministry found that even small amounts of the insecticide, imidacloprid, could cause problems such as the disruption of the bees’ “ability and desire to feed and forage” (Peters 2012, p. 618). Initially the French government intended to continue research on Gaucho while allowing the product to still be sold and used. But members of France’s National Association of French Beekeeping (UNAF) were angered by this news and marched through the streets of Paris protesting against the continuation of Gaucho and for the suspension of the insecticide (Peters 2012). Due to previous findings and the urging of French beekeepers, the French Agriculture Ministry issued a “two-year nationwide ban on the use of Gaucho as a sunflower seed treatment and commissioned a round of studies” (Peters 2012, p. 618). This ban was lengthened for an additional 2 years until Gaucho was permanently banned in 2003 (Peters 2012). The next year, Gaucho-treated maize was banned after scientists discovered the chemical was killing caretaker bees.

France’s honey bee population did not immediately recover after the banning of Gaucho, this thought to be because “the chemical remains in the soil for several years, where new plant absorb it through their roots” (Peters 2012, p. 619). Another reason for the slow recovery of honey bee populations could be that although the use of Gaucho on sunflowers was banned in 1999, the insecticide was still used on maize crops until 2004. France’s bee population did and has improved since the banning of Gaucho with Henri Clement, President of France’s National Association of Beekeepers, stating in 2008 that “colony loss had returned to its natural annual level” (Peters 2012, p. 619).

Colony Collapse Disorder in the United States

Though France experienced and essentially solved the large-scale disappearance of their honey bees, it seems much of the world is a decade behind. Though the number of honey bees in the United States has been on a slow descent since the 1950s, the disappearance of the pollinator accelerated in 2006 when bee colony losses increased from 17–20 % to more than 30 % (Johnson 2010, p. 5). Dave Hackenberg, a well-known commercial migratory beekeeper in Florida, was the first to bring attention to the issue when the experienced apiarist lost substantial amounts of his honey bees that winter. In November 2006, Hackenberg contacted Pennsylvania State University entomologist Dennis Van Engelsdorp who formed a task force to search for answers. By the following February “Hackenberg had lost 1900 of his 2900 hives,” and by June, over 2,100 hives were gone, costing Hackenberg approximately \$460,000 (Peters 2012, p. 620). Soon, other beekeepers in the United States and around the world began to report that their bees were disappearing, with some losing as many as 90 % of their hives (Peters 2012, p. 620). Canada, Central America, South America, Asia, and Europe experienced the effect of colony collapse disorder, bringing the crisis to national headlines.

By the spring of 2007, approximately one-third of the United States’ bees were affected by CCD and gone (Peters 2012). Annual hive loss averages approximately 30 %, which is nearly double what it was before 2006 (Peters 2012).

Potential Causes of Colony Collapse Disorder

As the loss of honey bees continues, scientists and beekeepers continue to scratch their heads and ponder the causes of colony collapse disorder. Some early theories seemed farfetched and were eventually thrown out such as a Russian conspiracy theory, the cell phone tower theory, or the idea that high-voltage transmission lines were the cause (Peters 2012). Other potential causes were

accredited to CCD, including climate change, malnutrition, droughts, and stress (Peters 2012). While some of these theories were thrown out early, scientists continued to search for the potential causes of CCD.

While early research proposed that causes of CCD were caused by pathogens, parasites, environmental stresses, and bee management practices, scientists later revealed that it seemed that no single factor was solely responsible for colony collapse disorder, but instead, the significant loss of honey bees was due to a combination of these stressors (Johnson 2010). Researchers “wonder whether a combination of stressors, including mites, disease, and nutritional stress, are interacting to weaken bee colonies,” making them more susceptible to stress-related pathogens (Johnson 2010, p. 9). A commonly agreed-on idea is that honey bees’ immune systems are in fact weakened, whatever the cause, making them susceptible to pathogens and other stressors. This results in the final collapse of honey bee colonies (Peters 2012, p. 264).

Scientists focus on the theory that CCD is caused by a combination of factors with the three main suspects being pesticides, “a new parasite or pathogen that may be attacking honey bee. . .,” and “a combination of existing stresses that may compromise the immune system of bees” (Johnson 2010, p. 9).

Pesticides and Colony Collapse Disorder

Commonly used pesticides have been suspected as a cause of CCD since honey bees began disappearing in 2006. As discussed earlier, France experienced a large loss of honey bees that was eventually contributed to systemic pesticides that are now outlawed in the country. But the dangers of pesticides were acknowledged before 2006. In fact, in 2003, the EPA recognized that traces of clothianidin residue found in nectar and pollen were toxic to honey bees as well as other pollinators (Peters 2012, p. 264).

Neonicotinoid pesticides can be applied using multiple methods, offering various ways honey bees and other pollinators can be exposed to the toxic chemical. Honey bees can be exposed to

pesticides both indirectly and directly. Systemic pesticides are applied to seeds and remain in the plant as it grows. Because of this, neonicotinoids can remain in the soil and even grow in new plants. Being an insecticide, the purpose of neonicotinoids is to kill insects, this being done by blocking nerve impulse pathways in honey bees, causing paralysis (Peters 2012, p. 264). Blockage of these pathways is thought to affect the communication and navigation of honey bees.

In 2003, the EPA required Bayer CropScience, the maker of the clothianidin, to research on the sublethal effects their product had on honey bees (Peters 2012, pp. 625–626). While this research was conducted, conditional registration was granted to the company, allowing their product to remain on shelves despite its potential harm to pollinators (Peters 2012, p. 626). After questionable research was conducted by Bayer, the EPA accepted the study as “scientifically sound,” and the product was allowed to be marketed for use on “corn, canola, soy, sugar beets, sunflowers, and wheat” (Peters 2012, p. 626). Bayer attempted to add to this list in 2010, but failed when the EPA found that there were deficiencies recognized as well as unknown toxic effects that could cause potential damage to pollinators (Peters 2012, p. 626). The EPA therefore required another field study be conducted. Since 2010, the EPA has yet to revoke clothianidin’s registration, allowing the product to still be marketed and sold to farmers nationwide (Peters 2012, p. 628).

Researchers attempting to find and solve the cause of CCD have looked at pesticides as a potential cause. Penn State University’s research team is looking into the effects chemicals such as herbicides, fungicides, pesticides, and miticides have on honey bees (Peters 2012, p. 628). They believe that many of these products are released onto the market without ample research being conducted. In attempt to solve these problems, scientists are “focusing on synergistic and sublethal effects of multiple pesticides on the chemical senses and chemically mediated behaviors of honey bees in relation to honey bee health and CCD” (Peters 2012, p. 627). Researchers are looking at the effects of pesticide exposure past the application period and the effects this has on the environment as well as pollinators. Inactive

ingredients of these products are being studied as well, which potentially pose more of a threat than the active ingredients that are usually tested (Peters 2012, p. 627). Although there have been strides taken to discover the role pesticides play in the disappearance of honey bees, scientists are still eluded by this question.

Parasites, Mites, and Pathogenic Diseases

As previously discussed, parasites and pathogens played a role in the slow decline of bee colonies before 2006, but scientists believe that these stressors may have a more deadly impact due to the addition of other stressors and the emergence of new or newly more virulent pathogens, though it is unsure how significant this role is (Johnson 2010, p. 9). A USDA study found after dissecting bees that the honey bees are most likely not suffering from one single disease but instead, a multitude of pathogens and diseases that compromise the immune systems of the honey bees (Johnson 2010, p. 9).

The tracheal mite (*Acarapis woodi*) is making a comeback as honey bee populations decrease. In turn, mites can lead to smaller bee populations, causing a sort of snowball effect (Sammataro et al. 2000, p. 520). An indicator of tracheal mite infection includes weakened crawling bees with disjointed hind wings (Sammataro et al. 2000, p. 520). Hives infected with tracheal mites will also be abandoned with the bees leaving behind honey (Sammataro et al. 2000, p. 520). Honey bees are most affected by the tracheal mite in the winter season when bees are more obligated to stay in their hives and out of the cold (Sammataro et al. 2000, p. 524).

Varroa mites (*Varroa destructor*) were considered a suspect for colony collapse disorder, but beekeepers and scientists soon found that the mites were only found in some of the hives infected with CCD. Bee corpses would be evident if varroa mites killed honey bees; this is not the case with abandoned hives. Although the varroa mite may not be the single cause of CCD, research does suggest that the parasite does play a large role in the disappearance of honey bees (Comman et al. 2012, p. 10).

Varroa destructors carry and transmit diseases such as deformed wing virus and Israeli acute paralysis virus (IAPV), spreading them through parasitism. Israeli acute paralysis virus (IAPV) was first identified in Israel in 2004. The virus can infect both adult bees and brood. Symptoms include wing shivering followed by paralysis (Coenan-Davis 2009, p. 184). The disease only takes a few days to kill of infected hives, leaving dead bees outside of hives (Coenan-Davis 2009, p. 185). Although IAPV can be transmitted by varroa mites, it can also be transmitted orally through mouth-to-mouth contact or the cleanup of fecal matter (Sammataro et al. 2000, p. 532).

The origin of IAPV is uncertain. Scientists have hypothesized that this once isolated virus was brought in with the imported Australian honey bee and is potentially the trigger or cause of colony collapse disorder (Chen and Evans 2007, p. 1027). The USDA's Department of Agriculture Bee Research lab's Jeff Petitis introduced another hypothesis concerning the arrival of IAPV, believing that it may have been introduced into the United States through royal jelly imported from China (Chen 2007, p. 1027). Though Israeli acute paralysis virus has a high mortality rate, there is no proof that the disease is the single cause of CCD, this fitting in with the "cumulative effect" theory shared by most scientists (Johnson 2010, p. 9).

Like mites and diseases, fungi have also been viewed as a threat to honey bee populations. *Nosema ceranae* can eliminate colonies in a short period of time. First identified in 1996, this unicellular parasite also known as nosema is common among honey bees (Chen et al. 2008, p. 186). The microsporidian has been found in healthy colonies, giving scientists reason to believe the fungus only plays a small part in, if any, in colony loss (Chen et al. 2008, p. 186). *Nosema* lives in the midgut of honey bees where infection takes place (Chen et al. 2008, p. 186). With little external symptoms, it can be difficult to diagnose, but infection does cause digestive disorders, shortened life spans, as well as the decrease of colony size and honey production (Chen et al. 2008, p. 186).

A spore-forming bacterium known as *Paenibacillus larvae* is responsible for American foulbrood (AFB), a common and serious disease that infects the brood through indigestion of the spores, which will attack the larvae's gut (Genersch 2010, p. 511). A colony infected with AFB will lower production in honey, propolis, pollen, royal jelly, and beeswax (Genersch 2010, p. 510). Signs of American foulbrood are evident with shriveled dead larvae being a tan to dark brown in color. Irregular brood patterns will also be noted (Genersch 2010, p. 511).

Another larvae killer is the *Ascosphaera apis* responsible for chalkbrood. Chalkbrood derives its name from the larvae mummifying and turning white or a gray in color after ingesting the fungal spore (Aronstein and Murray 2010, p. S20). Transmission of the disease can occur through infected pollen combs being brought into a healthy hive (Aronstein and Murray 2010, p. S20).

Autopsies of sick honey bees have helped in solving the disappearance of honey bees. "High levels of bacteria, viruses, and fungi have been found in the guts of recoverable dead bees (Johnson 2010, p. 10)." The Pennsylvania Department of Agriculture discovered scar tissue in the bellies of honey bees along with undigested grains of pollen while performing autopsies. A possible meaning of this is that the honey bees were eating but were unable to digest their food or gain nutrition. Fungi were also found in the bees' tissues, suggesting suppressed immune systems.

Management Practices and Commercial Migratory Operations

Researchers have speculated that management practices have something to do with colony collapse disorder. With a 10–30 % die-off being common during transportation, commercialization is thought to be a benefactor to the decline in the health of the honey bee with a high percentage of those affected by CCD being commercial migratory beekeepers (Johnson 2010, p. 3; Coenan-Davis 2009, p. 181). Increased transportation and poor nutrition are the two main results

of the commercial beekeeping industry that has been growing since the early 1960s (Aizen and Lawrence 2009, p. 916). Commercial migratory operations often move bees across the country or up the coast “two to five times during a growing season,” causing a great deal of stress on these pollinators (Johnson 2010, p. 9). “Factors such as confinement and temperature fluctuations” are seen as potential causes in the current disorder, increasing the honey bee’s susceptibility to diseases and pests (Johnson 2010, p. 9).

While on the road, migratory beekeepers feed their bees high-fructose corn syrup and other substitutes. When reaching their destination, the bees are released to forage on single crops known as monocultures. Backyard beekeepers often compare this to feeding a kid only Snickers bars, viewing management practices as unsustainable and unhealthy for the bees. Though migratory beekeeping has been strongly blamed for the disappearance of honey bees, the industry plays a vital role in the US agricultural system.

Malnutrition

Many believe that malnutrition is a factor causing the weakening of the honey bee immune systems (Coenan-Davis 2009, p. 181). Though the loss of biodiversity may not be a primary cause in the disappearance of the honey bee, habitat loss can be linked to malnutrition, which weakens honey bees’ immune systems and makes them more susceptible to diseases and parasites (Coenan-Davis 2009, p. 181). Habitat loss can be accredited to agriculture, grazing, fragmentation, and development (Coenan-Davis 2009, p. 181). Due to monocultures, honey bees are forced to pollinate one single crop most of the time (Coenan-Davis 2009, p. 181). Honey bees need a variety of flowers for nectar and pollen sources. Monocultures have taken over once diverse farmlands and are environmentally unsustainable, compromising wild vegetation. Because there is no diversity in monoculture crops, pests are easily able to spread throughout crops, destroying them.

Artificial Queen Insemination and Genetic Loss

A trend of selective breeding and artificial insemination practices are increasing in response to Colony Collapse Disorder. The commercial beekeeping industry relies on approximately 500 breeder queens to produce the millions of queens used to start colonies, potentially causing a “genetic bottleneck” (Ellis et al. 2010, p. 135). While many believe that selective breeding can save the honey bee, others are concerned that this is only a temporary solution that could be more damaging in the future.

Conclusion

Many have joined efforts to discover the cause(s) and solutions of colony collapse disorder including the US Department of Agriculture (USDA) (Coenan-Davis 2009). In 2007, the Agricultural Research Service, summoning over “eighty bee scientists, extension agents, and industry representatives to identify areas where more information was needed and to prioritize additional research projects related to CCD,” hosted a Colony Collapse Disorder Research Workshop (Peters 2012, p. 622). From this, a CCD Steering Committee and a CCD Research Action plan was developed in attempt to find the causes of CCD. The following year, Congress appropriated funding for research and surveillance of US honey bees (Peters 2012). This farm bill directed the Secretary of Agriculture to annually submit a report describing the USDA’s progress in investigating the causes of CCD and strategies formed to reduce the loss of honey bees (Peters 2012, pp. 622–623).

Questionnaires and surveys have been given to beekeepers in attempt to better understand hive management practices and environmental factors that were shared by beekeepers affected by colony collapse disorder. Even though research has continued, the Agricultural Research Service has yet to discover the original factor that is responsible for the mass disappearance of honey bees in 2006 (Peters 2012, p. 599).

Introduction

Current rates of species loss exceed those of the historical past by several orders of magnitude and show no indication of slowing. Major drivers of biodiversity loss on a global scale are land-use changes and agricultural intensification. These processes are threatening ecosystem functioning and services on which humans depend. Biodiversity contributes directly through provisioning, regulating, and cultural ecosystem services and indirectly through supporting ecosystem services to many constituents of human well-being. In consequence, there is deep concern that a loss of biodiversity and deteriorating ecosystem services contribute to worsening human health; higher food insecurity; increasing vulnerability of ecosystems to natural disasters; lower material wealth; worsening social relations by damage to ecosystems highly valued for their aesthetic, recreational, or spiritual values; and less freedom for individuals to control what happens and to achieve what they value (see detailed explanations in MEA 2005). Growing awareness of the importance of biodiversity for human well-being has led governments and civil society to a clear set of conservation targets aiming to significantly reduce biodiversity loss in the near future (see Convention on Biological Diversity; www.cbd.int). One of these targets (target 7 of the recent Strategic Plan for Biodiversity 2011–2020) demands that by 2020 areas under agriculture, aquaculture, and forestry are managed sustainably, ensuring conservation of biodiversity.

This entry addresses the importance of agricultural biodiversity on the one hand and the role of agriculture in the rapid decline of global biodiversity on the other hand. It also presents ways how agricultural production can provide essential goods for a growing world population but at the same time sustain biodiversity and the stability and functioning of ecosystems.

Agricultural Biodiversity

Agricultural biodiversity is an important subset of biodiversity. According to the Convention on

Biological Diversity (COP 5 Decision V/5), agricultural biodiversity includes all components of biological diversity of relevance to food and agriculture and all components of biological diversity that constitute agricultural ecosystems: the variety and variability of animals, plants, and microorganisms, at the genetic, species, and ecosystem levels, which are necessary to sustain key functions of the agroecosystem, its structure, and processes. Agricultural biodiversity comprises the diversity of genetic resources (varieties, breeds) and species used for food, fodder, fiber, fuel, and pharmaceuticals. It also includes the diversity of non-harvested species that support production (soil microorganisms, predators, pollinators) and those in the wider environment that support agroecosystems (agricultural, pastoral, forest, and aquatic) as well as the diversity of the agroecosystems.

Agricultural biodiversity is a fundamental feature of farming systems around the world. Since the beginning of agriculture some 10,000 years ago, farmers made use of a variety of plants and livestock and have employed numerous practices to enhance diversity in and around their agricultural land. Agricultural biodiversity is an important source of traits to improve crops and livestock, for example, conferring resistance to diseases, pests, and parasites or the ability to withstand high temperatures, droughts, or frost. It contributes to the quality of nutrition and might help to buffer against environmental alterations such as climate change but also against economic adversities. Agricultural biodiversity is also a key asset to improve the livelihoods and productivity of small-scale farmers in developing countries. Smallholders farm on less than two hectares and account for 90% of farmers worldwide. They strongly depend on a rich diversity of native plant varieties and locally adapted animal breeds for their livelihoods and survival and are increasingly recognized as important stakeholders to guard biodiversity.

In Europe, traditional low-intensity farming practices increased biodiversity for millennia. By altering comparatively low-diversity forests into farmland, new habitats were created and enriched by plant and animal species migrating from neighboring biogeographical areas such as

the Asian steppes. For a long time, European agricultural landscapes were thus characterized by a rich diversity of land uses, sizes and shapes of fields, as well as seminatural elements such as hedgerows. Such heterogeneous landscapes support high species richness, both above- and belowground, but are severely threatened today by either agricultural intensification or land abandonment.

Green Revolution and the Loss of Biodiversity

The conversion of land from complex natural ecosystems to simplified agricultural ones and the intensification of agriculture have been and still are major causes of the decline of global biodiversity. Since the advent of the green revolution in the early 1960s, global arable land has increased by 67 million hectares as the result of two opposing trends: an increase of 107 million hectares in developing countries, mainly due to habitat conversion in areas of high biodiversity in the tropics, and a decrease of 40 million hectares in developed countries, mainly due to yield improvements.

Intensification of agricultural systems coupled with specialization by plant breeders and the harmonizing effects of globalization have led to a substantial reduction in the genetic diversity of domesticated plants and animals in agricultural systems. For example, a third of the 6500 breeds of domesticated animals are currently threatened with extinction due to their very small population sizes (MEA 2005). Moreover, of the several thousand plant species which have been used for human food in history, at present only about 150 are commercially important, and about 103 species account for 90% of the world's food crops. Just three crops, i.e., maize, rice, and wheat, supply almost 60% of the calories and proteins derived from plants (FAO 2012). According to the FAO, about 75% of the genetic diversity of agricultural crops has been lost over the last century, and this genetic erosion continues. It is feared that genetic homogenization decreases the potential of species to cope with short-term challenges such as pathogens and

herbivores or to persist in the face of environmental changes such as droughts.

Intensive agriculture relies on external inputs such as chemical fertilizers, pesticides, herbicides, and water for crop production and artificial feeds, supplements, and antibiotics for livestock and aquaculture. These practices are hardly sustainable. They damage the environment, undermine the nutritional and health value of foods, lead to reduced function of essential ecosystem services, and result in a severe loss of biodiversity (FAO 2010). Synthetic production of nitrogen fertilizer has been identified as *the* key driver for the increase in food production over the past 60 years. More than half of all the synthetic nitrogen fertilizers ever used on Earth have been used since 1985, and humans now produce more reactive, i.e., biologically available, nitrogen than is produced by all natural pathways combined. Several studies have shown that aerial deposition of nitrogen into natural terrestrial ecosystems such as heathlands or grasslands leads to a significant reduction in plant species richness (e.g., Kleijn et al. 2009; Maskell et al. 2010).

In many European countries, a serious decline of farmland birds has been observed due to agricultural practices. Of the 58 species classified as being primarily birds of farmland, 41 showed negative overall mean trends across Europe. Cereal yield alone explained 30% of the variation in bird population trends and can thus be used as an indicator for reduced suitability of habitats and availability of food for farmland birds (Donald et al. 2006).

Challenges for Agriculture and Ways to Counter the Loss of Biodiversity

A major challenge for agriculture in the twenty-first century is the provision of basic goods for a growing world population that will reach approximately nine billion by 2050. It has been predicted that the demand for food and fiber will grow by 70–100% within the next four decades and that a further 10–20% of grassland and forestland has to be converted for agricultural uses, leading to a global extinction of species (MEA 2005). This

would also mean an almost threefold increase in nitrogen- and phosphorus-driven eutrophication of ecosystems, with phosphorus stocks running out by the end of this century and an increasing demand for water (agriculture already accounts for 70% of global use). In consequence, an increasing competition for land, water, and energy is expected that, together with predicted climate changes, will affect agriculture in the future.

To counter the loss of biodiversity, agricultural production practices need to change. There are multiple, not mutually exclusive, ways agricultural production can provide sufficient, safe, and nutritious food but at the same time sustaining biodiversity and the stability and functioning of ecosystems. Organic farming is one way to improve on-farm sustainability and is already used by many farmers around the world. Other approaches, for instance, deal with sustainable intensification, multifunctionality, multispecies use, the use of genetically modified (transgenic) crops, and the support of smallholder farming. All of these approaches greatly depend on geographical conditions, national and international policies, consumer behavior, and other factors, and it would be pointless to come forward with one global strategy towards agricultural sustainability. Instead, multiple strategies are needed that take into account the specific conditions of a country or region.

Organic Farming

Organic farming worldwide rose by almost 30% in the last decade. In 2009, about 38 million hectares of land were organically farmed (FAO 2012). Organic farming is a holistic production management system which promotes and enhances agroecosystem health, including biodiversity, biological cycles, and soil biological activity. It emphasizes the use of management practices in preference to the use of off-farm inputs, taking into account that regional conditions require locally adapted systems. General principles and requirements for organic farming are defined in the Codex Alimentarius guidelines adopted in 1999. According to these guidelines, an organic production system is designed to enhance biological diversity within the whole system, increase

soil biological activity and maintain long-term soil fertility (by minimum tillage or zero tillage operations), recycle wastes of plant and animal origin in order to return nutrients to the land, thus minimizing the use of non-renewable resources and avoid pesticide and herbicide use.

Research indicates that organic compared to conventional farming significantly increases soil biological activity, biomass, and abundance of earthworms and arthropods, plant species diversity, and microbial diversity (Mäder et al. 2002). Organically manured, legume-based crop rotations utilizing organic fertilizers from the farm itself are efficient in resource utilization, enhance floral and faunal diversity, and are thus a realistic alternative to conventional farming systems. The deficits of organic agriculture, mainly related to lower yields, should not be exaggerated. Lower yields (about 20%) in organic than conventional farming occur mostly in cash-crop-focused production systems and under most favorable climate and soil conditions.

Sustainable Intensification

The environmental impacts of doubling global crop production until 2050, as predicted, will depend on how increased production is achieved. Agricultural production could be increased by either extensification or intensification. While extensification would imply the clearing of additional land for crop production, intensification would mean to achieve higher yields through increased inputs, improved agronomic practices, improved crop varieties, and other innovations. It has been predicted that, if yield growth did not materialize, an estimated one billion additional hectares of land would be needed to meet current demands. At present, agricultural land expansion takes place especially in countries of sub-Saharan Africa that combine growing needs for food and employment with limited access to technology that could increase intensification of cultivation on land already in agricultural use (FAO 2012). Most of these countries still harbor high biological diversity and are thus especially vulnerable to habitat changes.

A trajectory that adapts and transfers technologies to underyielding nations, enhances their soil fertility, employs more efficient nutrient use, and minimizes land clearing could be a more promising path to environmentally sustainable intensification and equitable global food supplies than extensification. Under the assumption that current trends of greater agricultural intensification in richer nations and greater land clearing (extensification) in poorer nations were to continue, it has been calculated that about one billion ha of land would be cleared globally by 2050, with CO₂-C equivalent greenhouse gas emissions reaching 3 Gt and N-use 250 Mt. per year by then. In contrast, if 2050 crop demand was met by moderate intensification focused on existing croplands of underyielding nations, adaptation and transfer of high-yielding technologies to these croplands, and global technological improvements, the analyses forecast land clearing of only about 0.2 billion ha, greenhouse gas emissions of 1 Gt per year, and global N-use of 225 Mt. per year (Tilman et al. 2011).

Multifunctionality, Decoupled Farm Program Payments, and Agri-environment Schemes

Modern agricultural policy in Europe addresses the loss of biodiversity in cultured landscapes with an increasing share of direct payments for non-consumptive services of agriculture, so-called public goods. The decoupling of partly area-related direct payments from production payments to reward multifunctional services represents a substantial reform of the European Union's Common Agricultural Policy. Direct payments should secure the conservation of biodiversity and the sustainable development of traditional cultural landscapes through, for instance, agri-environmental schemes. In the United States, so-called green payments are envisaged that will reward farmers and ranchers for sound land management and resource conservation. Environmental benefits could include sequestering carbon, controlling floodwaters, providing wildlife habitats, recharging groundwater, increasing biodiversity, and providing open space and cleaner air and water.

In Europe, agri-environment schemes are important political instruments to counteract the

loss of biodiversity in agricultural land and to foster ecosystem services such as pollination and natural pest control. However, such schemes vary markedly between European countries. In Switzerland, the Netherlands, and the United Kingdom, for instance, they focus mainly on wildlife and habitat conservation, whereas in Denmark and Germany they focus on the reduction of agrochemical emissions and in France on the prevention of land abandonment in agriculturally marginal areas (overview in Kleijn and Sutherland 2003). In Switzerland, farmers can qualify for area-related direct payments if they meet a number of environmental standards. One of these standards, regulated by the Swiss Federal Legislation, demands that farmers have to manage at least 7% of their utilized agricultural land as so-called ecological compensation areas. Farmers are free to choose the types of ecological compensation areas for their land which encompasses traditional landscape elements (most often extensively managed hay meadows) and elements newly designed for the purpose of biodiversity conservation (e.g., wildflower strips sown with seed mixtures of herbaceous plant species). In alpine regions, farmers are encouraged with the help of subsidies to maintain or reestablish species-rich nutrient-poor grasslands which are currently strongly threatened either by intensification or abandonment.

Agri-environment schemes have been evaluated in several studies, most of them showing positive results for plants, birds, various groups of insects, and vascular plants. In the United Kingdom, agri-environment management has reversed declines in the populations of several bird species of high conservation concern such as the Corncrake *Crex crex* (Wilson et al. 2009). In Switzerland, ecological compensation areas resulted in an enhancement of both pollinator species richness and abundance and pollination services to nearby intensely managed farmland (Albrecht et al. 2007). It has frequently been suggested that there might be a disjuncture between the visual aesthetic quality of landscapes and their ecological value, leading to conflicts in the setting of conservation priorities and management aims. However, the results of recent studies suggest otherwise. Both species richness

and structural diversity in grasslands were found to be an important predictor for a positive aesthetic valuation of agricultural landscapes (Lindemann-Matthies et al. 2010).

Plant Diversification in Agricultural Systems

Experiments in which biodiversity was manipulated have shown that diversity influences many ecosystem functions. At eight European field sites, the impact of loss of plant diversity on primary productivity was simulated by synthesizing grassland communities with different numbers of plant species. There was an overall log-linear reduction of average aboveground biomass with loss of species (Hector et al. 1999). Recent results from a long-term experiment in the United States suggest that the use of diverse mixtures of species may be as effective in increasing productivity of some biomass crops as ecologically relevant changes (Tilman et al. 2012). In the experiments, a change in plant diversity from one to 16 species caused a greater biomass increase than the application of 95 kg nitrogen per ha and year or other treatments such as CO₂ enrichment, water addition, and the exclusion of herbivores. A recent meta-analysis also depicts strong evidence of a positive impact of plant diversification on agricultural systems. Herbivore suppression, enemy enhancement, and crop damage suppression effects were significantly stronger on diversified crops than on crops with none or fewer associated plant species (Letourneau et al. 2011).

The Use of Genetically Modified Crops

During the past 20 years, genetically modified crops have become increasingly important in agriculture. The innovation of GM crops was sold as a promising avenue to increase agricultural productivity and thus food supply safety for a growing world population and, at the same time, to minimize the impact of agriculture on farmland organisms and ecosystems by reducing fertilizer and pesticide use. From 1996 (first commercial cultivations) to 2011, the area globally cultivated with GM crops has increased from 1.7 to 160 million ha, especially in developing and newly industrializing countries. Today, GM crops (mainly soybean, maize, and cotton) are cultivated by 16.7

million farmers in 29 countries, with the United States, Brazil, and Argentina as major cultivators (James 2011). Less than 1% of total commercial releases have been executed in Europe, where use and production of GM crops are met with a growing skepticism among consumers. Moreover, EU policies regard GM crops and food as results of a specific production process and are thus much more restrictive than, for instance, US policies which roughly apply the same regulatory framework to GM as to non-GM crops and food.

The two dominant traits of GM crops are herbicide tolerance and insect resistance which are often combined. Proponents of transgenic crops, mainly representatives of research communities and transnational corporations, argue that herbicide-tolerant crops will enhance farmland biodiversity as herbicides can be sprayed and weeds do not have to be removed by massive tillage operations prior to crop seeding. In consequence, tillage operations are reduced, soil organic matter increased, and erosion and water loss decreased. Likewise, insect-resistant crops are thought to reduce pesticide use and thus contribute to biodiversity conservation.

Ecological arguments against GM crops include concerns that transgenes might escape into wild populations, that the use of herbicide-resistant GM crops might lead to an increase in spraying herbicides, and that toxins produced by GM crops might enter the food web and thus affect nontarget organisms. Cases of intraspecific gene flow have already been reported, for instance, in maize (Piñeyro-Nelson et al. 2009). Moreover, it should be noted that biotechnology cannot design new genes but has to rely on the existing diversity of genetic material to move desirable traits from one organism to another.

Support of Small-Scale Farming in Developing Countries

International organizations such as the FAO, but increasingly also ecologists and other researchers, advise to support small-scale farming and to strengthen its efficiency especially in tropical regions which are hotspots of biodiversity. Small-scale farming allows patches of natural vegetation to remain which provide valuable habitats for

pollinators, species that prey on pests or weeds or in other ways contribute to beneficial ecological processes. Moreover, due to the use of multispecies and genetically heterogeneous local landraces, small-scale farming can buffer against environmental adversities and is thus rather resilient to environmental alterations such as climate change.

On the other hand, small-scale farming is highly vulnerable to market developments. Recently, international investors have been increasingly leasing or buying farmland in Africa, Asia, and Latin America (land grabbing). Main investors are food-importing countries with land and water constraints but rich in capital such as the Gulf States or countries with large populations and food security concerns such as China, South Korea, and India (FAO 2010). They invest in farmland overseas, especially in tropical and subtropical regions, where production costs are lower, land and water more abundant, or climatic conditions more suitable for the production of staple or biofuel crops. As a result, low-intensity smallholder land is converted to intensively managed production units, further diminishing global biodiversity and ecosystem functioning.

Summary

Changes in biodiversity due to human activities were more rapid in the past 50 years than at any time in human history, with agriculture as a major driver of biodiversity loss. Biodiversity loss and especially the loss of genetic diversity in both wild and domesticated organisms are reducing overall fitness and adaptive potential of species and are threatening ecosystem functioning and services on which humans depend. For fear of genetic erosion, biodiversity is now conserved *ex situ* in gene banks or breeders' materials. The Millennium Seed Bank Project, for instance, wants to insure against the extinction of plants in the wild by storing seeds for future use. In 2009, it reached its 10% target of banking the entire world's wild plant species.

Both the maintenance of biodiversity and the provision of basic goods for a growing world population are global responsibilities. Organic

farming, sustainable intensification, multifunctionality, multispecies uses, and support of smallholders for more efficient, profitable, and sustainable production are just some ways to preserve and use biodiversity better in agricultural areas while meeting increasing demands for food, fiber, and other agricultural products. Making consumers aware about food production that is done in environmentally, socially, and ethically acceptable ways could be another important step towards sustainable agriculture, biodiversity conservation, and global equity.

Biodiversity and Global Development

John Vandermeer

Department of Ecology and Evolutionary Biology, University of Michigan, Ann Arbor, MI, USA

Introduction

There is general agreement that the world's biodiversity is being degraded at a phenomenal rate, perhaps far more rapidly than the popular press has reported. Proponents of conservation suggest that optimism is warranted in that there seems to be universal concern over this surging problem. From the point of view of values and ethics, who can be against the conservation of biodiversity? This *cause célèbre* enjoys universal approbation from all sectors of all societies. Yet balancing the costs and benefits of conservation is a complicated issue, and approbation becomes less universal in specific case studies.

For example, local farmers in the Global South may see large mammalian carnivores as threatening to their children. Developers in the Global North may see attempts at preserving a threatened species of snail or fish as threatening to their aspirations. And the fundamental problem of thinking of biodiversity as nothing more than big charismatic creatures living in pristine environments remains a major stumbling block to devising effective programs to engage this truly worldwide problem. Small things like fungi and insects do not get the same attention as elephants and mountain gorillas. Such large charismatic creatures represent a minor fraction of the world's

biodiversity, compared to the small things – mites, nematodes, insects, to say nothing of bacteria, the biodiversity of which remains largely enigmatic.

Global development has been uneven since World War II, with some parts of the world having experienced dramatic growth in economies and human wellbeing while others have seen stagnation. Analysis of this pattern is eclectic, complicated, and controversial, but there is agreement that the history of colonialism retains its mark, with neocolonial interference from the richer countries frequently creating barriers to development in the former (and sometimes current) colonies. Most of the poorer areas of the world are in the south and in contemporary discourse collectively are referred to as the “Global South,” while most of the richer areas are in the north and are referred to as the “Global North.”

There is an important connection between biodiversity and global development. We see this connection from an examination of the key patterns of both biodiversity and development (IAASTD 2009).

Patterns of Biodiversity

Among the global patterns of biodiversity, there are two that stand out as relevant to questions of development. First, species diversity tends to increase with decreasing latitude, a geographic pattern. Second, species diversity tends to decrease as the intensity of management of the ecosystem increases, an intensification pattern.

Examining biodiversity at different latitudes, there is a dramatic difference between temperate and tropical worlds (and thus between Global North and Global South). Forest surveys in the northern Europe, for example, will generally encounter between 2 and 20 species of trees per hectare, whereas such surveys in central Africa will encounter upwards of 300. The bird guide of Colombia lists 1695 species, while in all of North America (an area much larger), there are 700. Butterflies, ants, mammals, and amphibians all show this same pattern. There are exceptions, but the general pattern is one of increasing numbers of species as you approach the equator. The cause of this pattern has been the subject of an

enormous amount of speculation and debate in ecology and remains generally unresolved.

Examining different ecosystem management strategies, it is first necessary to distinguish between two concepts of biodiversity. First is the collection of plants and animals that the manager has decided are part of the managed system – rice in the paddies of Asia, corn and beans in the traditional fields of Native Americans, carp in the fish ponds of China, and so forth. This is referred to as the “planned” biodiversity. Additionally in each of these ecosystems, there is a great amount of biodiversity that spontaneously arrives – the aquatic insects and frogs in the Asian rice paddies, the birds and bugs that eat the Native American’s corn and beans, and the crayfish that burrow their way into the sides of the Chinese fishponds. This is referred to as the “associated” biodiversity. Frequently the managers themselves are determinedly concerned about the planned biodiversity, especially when dealing below the species level (i.e., genetic varieties of crops). Nevertheless, it is almost certainly the case that the associated biodiversity is the dominant form in almost all managed ecosystems.

The vast majority of managed ecosystems are agricultural. The particular form of agriculture has important impacts on biodiversity through several mechanisms. It has become common to order these mechanisms with the rubric of “intensification.” Although the term “agricultural intensification” has a very specific and complex definition in anthropology, in the biodiversity literature, the term “management intensification” is taken to be the transition from ecosystems with high planned biodiversity to low planned biodiversity. The ecology of the agroecosystems is such that the final stages of intensification usually involved the application of agrochemicals to substitute the function of some of the biodiversity that is eliminated. There are two basic patterns of associated biodiversity change that might be expected as a function of intensification. First, it is sometimes the case that with even a small alteration in natural habitat by some management system, associated biodiversity tends to fall dramatically. Second, it is sometimes the case that associated biodiversity declines by only small amounts with low levels of intensification and only after much higher levels are reached

do we see dramatic declines. Which of these two patterns (or what combination of the two) exists in particular systems remains largely unstudied.

Patterns of Global Development

Post WWII development has resulted in uneven distribution of prosperity and potential. Popularly referred to as the G8 (in 2013), the three nations of the British Empire (UK, USA, Canada), three western European nations (France, Germany, Italy), and Japan and Russia, these eight nations account for approximately half of the world economic activity. Other European nations are commonly included as members of the Global North. Most tropical countries are thought to be the major elements of the Global South, typified by low GDP, and thought to be in the developmental position due to historical circumstances, largely a result of the age of European Imperialism. More recently the economic changes in Brazil, South Africa, India, China, and Mexico have propelled them to a seemingly intermediate status, codified (as of 2013) as the Outreach Five.

In addition to the evident distinction economically between the Global North and Global South, there is also a distinction of geographic demography. In nations of the Global North, generally less than 35% of the population resides in rural areas, frequently far less (e.g., 11% in the UK, 20% in the USA), whereas in nations of the Global South, generally more than 50% lives in rural areas (e.g., 88% in Uganda, 81% in Cambodia). There are exceptions, but the general rule is that in the Global South, a large segment of the population lives in rural areas, which implies a large segment of the population involved in agricultural activities. From an ethical standpoint, development goals cannot ignore this segment of the population.

Intersection of Biodiversity and Global Development Patterns

There is thus this curious pattern in which the bulk of the world's remaining biodiversity exists in the same areas of the world where underdevelopment and poverty exist. This leads to important

contradictions in global goals. On the one hand, conservation of biodiversity must concentrate on the Global South, yet, on the other hand, poverty reduction in the Global South must promote rural development activities, many of which involve the intensification of agriculture, generating precisely the background conditions known to reduce biodiversity. There thus appears to be a contradiction between the goals of conservation of biodiversity and reduction of poverty.

Pursuing a resolution of this contradiction, scholars have proposed a variety of avenues, most of which can be broadly categorized into passive versus active. Of the passive approaches, some scholars suggest lessons from history. The European colonization of eastern North America began with massive deforestation to make way for the expansion of agriculture. Subsequently, through industrialization and related urbanization, agriculture declined and forests returned. The dynamics that drove this process are evident at a broad qualitative level – wealth from agriculture drives local industrialization that, in turn, acts as a magnet for labor, which depopulates the countryside, leaving natural succession to take over. This general view seems historically accurate and has been referred to as the “forest transition model” (FT model). Similar processes have been described for some European countries, the rural US south and most importantly, given its tropical location, Puerto Rico. Based on these and other examples, some scholars suggest that the FT model could be a framework for understanding tropical landscape dynamics in general and even be used for promoting a conservation agenda and, indirectly, poverty reduction through industrialization.

Ultimately, the FT model rests on two quantitative assumptions and a seemingly logical conclusion. The two assumptions are, first, a given population density requires a specified land base to enable productive activities adequate for survival of the whole population and, second, the amount of food required to support that population, divided by current per-area productivity, equals the land area necessary for agricultural production. The logical conclusion is that the total land area minus the area necessary for production is what is available for conservation. The

FT model has been criticized on the basis of many case studies in which the conditions for land abandonment seem to have been met, but the expected urbanization failed to follow.

The second set of approaches, the active approaches, include a variety of forms. One form is the land-sparing versus land-sharing debate. Assuming a certain amount of land will be devoted to food production (agriculture) and the rest to conservation, the question is whether the part devoted to food production should be intensified so as to produce more food per area (and thus have less land required to feed a fixed population, with more to “spare” for conservation) or whether the biodiversity contained in the agricultural land should be taken into consideration (“shared” with the biodiversity). Analyses have appeared supporting both points of view, seemingly dependent on the particulars of chosen case studies (Fischer et al. 2011; Perfecto and Vandermeer 2010; Tschamtké et al. 2012).

Other analysts see a resolution of this contradiction in the combination of recent understanding of the ecology of biodiversity and the grassroots politics of rural sectors of the Global South. Viewing the overall landscape as fragments of natural vegetation in a matrix of agriculture, basic principles of ecology point to the importance of the agricultural matrix as a corridor that provides a necessary connection between isolated fragments of natural habitat that contains much of the biodiversity. The activities of small-scale agriculturalists accord well with the construction of such “high-quality” matrices (Perfecto et al. 2009).

Introduction

This entry briefly explains and explores the history of biodynamic farming, including some of its key philosophies and food production practices. Biodynamic farming views a farm as a holistic entity, a microcosm in physical form of the macrocosm of the physical, ethereal, and astral form of the spiritual universe.

Rudolph Steiner

Biodynamics, or biodynamic farming, refers to a specific practice of agriculture that is based upon the work and teachings of the Austrian Rudolf Steiner (1861–1925). In order to understand biodynamic farming, one must first understand Steiner and his metaphysical belief system. Steiner was a prolific researcher and speaker, using his created method of “spiritual science” to study the inherent wisdom of humanity (anthroposophy). His research was based on his own spiritual and visionary experiences and

intuitive insights, as well as studies he undertook with Theosophists and readings he undertook in religious literature from around the world. His experiences and active teaching schedule resulted in the publication of over 40 books, and he was invited to give over 6000 lectures. Before dying, Steiner founded The General Anthroposophical Society in Switzerland in 1924. Besides providing the inspiration for biodynamics, Steiner was instrumental in creating or inspiring Waldorf Schools, Camphill villages, anthroposophic medicine, and eurythmy. Steiner was also a leading expert on Johann Wolfgang von Goethe's work, and the impact of Goethe on Steiner's thinking was recognized when Steiner designed the Goetheanum in Dornach, Switzerland, which serves as the headquarters of the global Anthroposophical Society.

Steiner's spiritual science is predicated on the belief that each person is on an evolutionary trajectory, occurring by incarnations over many lifetimes, toward self-realization/God-realization. By practicing and cultivating the spiritual insights taught by Steiner, individuals can advance along this evolutionary path and have visionary, gnosis-filled experiences. Thus, anthroposophy is a scientific approach to spiritual experiences of our innate divine wisdom. Steiner's cosmology borrows heavily from Theosophy, Germanic idealism, and Advaita Vedanta Vedic philosophy contained within the *Upanishads*, which speak of an eternal divine spark within each being that is on a path toward liberation via reunion into the Divine/God. Steiner taught that as a soul progresses through physical incarnations, so does humanity and the world. Steiner's view of the human is that the human contains a four-part body. The first is a physical body, based on the mineral world; the second is a life or etheric body, which causes the body to grow and vitalizes it, making it alive, and this body is associated with the plant world; the third is an astral body, which serves as the seat of consciousness and sentience, and is connected to the animal world; and the fourth body is the ego, or self-awareness. Taken together, Steiner's cosmology is of an interconnected, holistic cosmos, where etheric

and astral forces emanate from the cosmos and influence the development of all life on earth. This includes the evolutionary growth and development of animal life, plant life, and human spiritual and physical life. It is within this larger cosmology that biodynamics functions.

From June 7 to 16, 1924, Steiner gave eight lectures in German to a group of farmers on the "Spiritual foundations for the renewal of agriculture" at Koberwitz, Silesia (Steiner 2005). These farmers had expressed concern about noticed losses in yields and soil health, so Steiner was invited to provide insights into how to create remedies to this scenario. The mechanization and use of chemicals in agriculture was also about to begin, so Steiner's teachings became the basis of an alternative to what became the Green Revolution, and it is upon these lectures that biodynamic farming is based.

Biodynamic Farming Practices

Key insights from Steiner's lectures became the basis for biodynamics, and most every biodynamic farmer builds their own practice of farming upon these teachings. These include the teaching that a farm is a self-contained microcosm that mirrors the macrocosm. Thus, a farm should be managed as a holistic entity while recognizing that astral and etheric forces from the cosmos influence plant, animal, soil, and human health. It is upon this key teaching that unique biodynamic farming practices are built. The most unique of these is the creation and casting of biodynamic preparations, or "preps." In essence, biodynamic preps (BD preps) are a kind of homeopathy for the soil, bringing etheric and astral forces into the soil within which plants grow and upon which animals then graze and consume. The preps are meant to help a farmer create a microcosm of the macrocosm, where, by using the preps, astral and etheric forces are amplified on the farm, resulting in healthier, more spiritually dense and pure products. As these products are consumed, the human becomes more spiritually pure, and their evolutionary process in this

lifetime is thus sped up. Another key insight is the significance of cows, which Steiner saw as being in tune with astral and etheric forces, and especially cows with their horns intact; the horns act as a receiver of astral and etheric forces, and cows fed in grains and grass grown via biodynamic practices are seen as being the embodiment of health, so that their manure becomes the base of biodynamic composting.

Steiner spoke of various biodynamic composts and elucidated specific ways to make them. The composts are a mix of naturally occurring plants, mainly herbs, who possess etheric and astral properties that when potentized by rapid stirring in clockwise motion for 50 s, followed by 10 s counterclockwise, repeated for 60 min, are ready to be applied sparingly to a field. It is believed that by stirring them this way for such a long time, a spiritualized homeopathic tincture is created that activates the plant's etheric forces with the astral forces of the cosmos that are called in the vortex that is created while stirring. While he did not name them, the names BD 500–507 are how they have become to be known. These composts form the basis of biodynamic farming and are as follows:

- BD 500 – this is the basic “starter” compost tincture and works on building microbial activity in the soil, aids in root growth, and helps form soil humus. BD 500 is made by filling old cow horns with fresh cow manure and burying this under the ground for the winter months. Once dug up, the dung has been reduced to a fermented compost, and a pinch of this is added to pure water (ideally rainwater or from a pure spring or stream), potentized, and is spread over the fields in the spring as soil life forms resume activity after the winter (Mäder et al. 2002).
- BD 501 – this is ground quartz silica that is buried in cow horns over the spring and summer months. Quartz silica was seen by Steiner to be a very potent mineral. A pinch of silica is potentized in pure water and spread over growing plants. It is believed that this adds vitality and strength to plants and aids plant photosynthesis, thus allowing plants to hold off pests and blights.
- BD 502 – this is made from dried yarrow potentized in pure water and is added to plants as needed so that plants can attract trace elements and minerals from the soil, thus aiding in their growth and health.
- BD 503 – this is made from dried chamomile potentized in pure water and is added to compost piles and to the soil, as it is believed to increase soil life and health and thus stimulates plant growth.
- BD 504 – this is made from dried stinging nettle potentized in pure water and is believed to enliven the earth and soil, helping each individual plant obtain the nutritional components they need to be healthy.
- BD 505 – this is made from dried valerian potentized in pure water and is added to compost piles so that phosphorous will be properly used by the soil.
- BD 506 – this is made from dried dandelion potentized in pure water and stimulates the relationship between silicon and potassium, allowing them to work together to attract astral forces into the soil.
- BD 507 – this is made from oak bark potentized in pure water and provides healing qualities so that plants can combat harmful diseases.

Typically, 500 and 501 are made and added directly to the soil and plants 502–507 are potentized either in water or by stirring the dried herbs in fresh manure from healthy cows (ideally from cows with horns) for an hour, at which point they are added directly into a compost pile. The compost pile sits for a summer and over a winter, allowing the preps to become active homeopathically throughout the compost, and this compost is added to the fields the following year.

Key Figures and Developments

Steiner inspired his close contemporary, Ehrenfried Pfeiffer, who was instrumental in the development and dissemination of biodynamics. Other key figures in the development of biodynamic farming practices include Maria Thun, who developed a planting calendar based on the

position of certain key celestial bodies (a similar calendar is produced every year by *Stella Natura*); Alex Podolinsky, who is instrumental in bringing biodynamics to Australia, which has thousands of hectares currently devoted to biodynamic wheat and cattle (Podolinsky 1996); Josephine Porter, who formed the Josephine Porter Institute for Applied Bio-Dynamics, from where most North American biodynamic farmers receive the ingredients for BD preps; and Hugh Lovel. These and others have been instrumental in including the use of various rock powders on biodynamic fields (Stalin et al. 2010); and making connections between insights from fractal and chaos thinking and applying these to developing unique biodynamic methods of stirring water.

The Demeter label began in 1927, at which point they became the standard bearer of marketing biodynamic foods, and they have overseen international biodynamic standards since 1992. These standards regulate biodynamics in the production and marketing of grown food, cosmetics, manufactured textiles, and brand labeling. The International Biodynamic Association was founded in 2002, and they currently own and globally protect the trademark of Demeter and Biodynamic. Biodynamic wine is gaining in popularity, and overall acreage of grain crops grown with biodynamic methods has steadily been increasing. Biodynamic farming practices are now found in many of the world's farming regions, and an exciting recent development in biodynamics was the introduction of biodynamics to China, where BD preps and methods are used at the Phoenix Hills Commune outside of Beijing.

Summary

This entry provides a brief foundation about what is biodynamic farming, its key historical figures, and some of its key growing practices. If interested in learning more, the interested reader should consult some of the below literature (Mason 2011; Pfeiffer 2011; Tompkins and Bird 1998), purchase and consume biodynamic products, attend a workshop or training on biodynamics, and/or visit a biodynamic farm.

Introduction

Oil is one of the drivers of Western industrial societies. Our pattern and (increasing) quantity of oil consumption, however, is becoming more and more problematic for a number of reasons. First, oil and other fossil fuel stocks are finite and will at some point run out or become prohibitively costly to mine, both in economic and in environmental terms. Second, burning fossil fuels releases greenhouse gases into the atmosphere, thereby contributing to global climate change. Third, dependence on oil implies dependence on oil-producing countries – countries that might not always be politically stable or well disposed

toward oil-importing countries and thus threaten the importing countries' energy security (Landeweerd et al. 2009).

Biofuels have been hailed as a replacement that had the potential to address all those problems. First, biofuels are made from plants or algae ("fuel crops") that can be cultivated indefinitely, rather than coming from a limited stock. Second, biofuels were initially considered to be "carbon neutral," where the amount of carbon emitted during combustion would be the same as the amount stored in the plant during growth, leading to a net carbon emission of zero (however, see section "Land Use"). Third, fuel crops can be grown anywhere, though conditions in the (sub)tropics favor certain kinds of crops such as oil palms, which means that it lessens dependence on oil-producing countries. In addition, two arguments are often mentioned in favor of using biofuels rather than alternative energy sources for the transport sector: First, biofuels can be blended with fossil fuels and thus can utilize our existing infrastructure, whereas the switch to electric cars or a hydrogen economy would require massive infrastructural changes. Second, heavy-duty vehicles such as airplanes cannot as yet be powered by fuel cells or batteries but could be powered by biofuels (Nuffield Council on Bioethics 2011, p. 19, hereafter the NCB). In practice, however, many types of biofuels have not lived up to their promises or even exacerbated problems and created normative, practical, and political challenges besides. This entry aims to give an overview of ethical issues of biofuels and their treatment in the literature.

In particular, after giving an introduction on what biofuels are, this entry presents an overview of ethical challenges on two levels: the practical and policy level, where concrete ethical problems arise and are addressed by governments and advisory and regulatory bodies, and the theoretical level, where the choice of theoretical framework influences which problems and possible solutions are highlighted. Issues related to GM agriculture and intellectual property are not addressed here as those topics are covered elsewhere.

Biofuels and Ethical Frameworks

What Are Biofuels?

Biofuels are liquid fuels derived from biomass, which can be bioethanol (made from fermented plant sugar) or biodiesel (made from plant oil); this entry focuses on their use as transport fuels. Biofuels are usually categorized as belonging to the “first,” “second,” or “third” generation; while categorization may differ, this entry adopts that of the NCB (2011) by type of source used. Here, the first generation consists of fuel derived from food crops such as rapeseed, soy beans, and corn. The second generation consists of fuel derived from inedible plants such as switch grass or *Jatropha* or “waste material” such as stalks and leaves. The major promise of these types of crops is that they do not require farmland and grow on marginal soil and so do not compete with food crops. The third generation consists of fuel derived from algae that would not require farmland, as they could be grown in ponds or bio-reactors. Third-generation biofuels are still in an early phase of development, and little has been written on their ethical aspects (exceptions are McGraw 2009; Biello 2011). An overview of the generations, some examples, and their related promises can be found in Table 1.

Biofuels in Practice: Concrete Issues

This section discusses how biofuels have fared so far compared to their promises and what new issues have arisen. As different kinds of biofuels tend to have different costs and benefits and the promises of second- and third-generation biofuels are mostly tied to anticipated developments, this entry abstains from giving a

normative judgment regarding which kind of biofuel is “best.” Rather, the section is structured as a descriptive account of different issues and value trade-offs that occur in the context of bio-fuel production and use.

Food Versus Fuel

The strongest critique against first-generation biofuels, and also the strongest driver to develop subsequent generations, is the very idea of using food crops for fuel. Jean Ziegler, United Nations special rapporteur on the Right to Food, has called first-generation biofuels a “crime against humanity” as they threaten the human Right to Food. Several arguments have been given why using food crops for fuel is problematic. First, though biofuel production cannot straightforwardly be said to lead to rising food prices (NCB 2011, p. 30), selling food crops on the fuel market could influence the food market in various negative ways (Gomiero et al. 2010). This is exacerbated by the fact that cars require lots of biomass to go on: the common example cited in the literature is that filling the 25-gal tank of an SUV with pure corn-based ethanol would require over 450 lb of corn, which contains enough calories to feed one person for a year (e.g., Gamborg et al. 2011). Considered on a larger scale, this equation means that using food for fuel is in a sense throwing food in a bottomless pit, where even processing huge amounts of food crops will only offset a small percentage of our transport fuel consumption (Biello 2011; Gamborg et al. 2011). Many authors therefore stress that biofuels are by no means a comprehensive solution to the problems caused by oil dependence, but rather might have a place in an “energy portfolio” alongside other

B

Biofuels: Ethical Aspects, Table 1 Kinds of biofuels by source (classification according to NCB 2011)

Generation	Type	Examples	Promises
First	Food crops	Palm oil, soy oil, rapeseed oil (biodiesel); corn ethanol, wheat, sugar cane (bioethanol)	Renewable, carbon neutral, no dependence on oil-producing countries
Second	Nonfood crops	Switchgrass, <i>Miscanthus</i> , willow, <i>Jatropha</i> , “waste” materials (stalks, leaves, etc.)	Does not take up farmland, can grow on marginal soil
Third	Nonfood organisms	Algae	Does not take up farmland, relatively efficient photosynthesis compared to plants

renewable energy sources, together with efforts to conserve energy and make existing usage more efficient (NCB 2011).

Proponents of second- and third-generation biofuels are quick to point out that their proposed crops cannot be used as food and will thus avoid the food versus fuel trade-off. Indeed, one argument for converting “waste” plant material such as stalks and leaves into fuel is that it would be a more efficient use of existing food crops. However, another trade-off lurks here: in a sense there is little or no “waste” in agriculture as unused plant material is often composted or left on the soil. This serves a variety of purposes, such as preventing soil degradation and erosion, maintaining soil ecology, and converting arable land into carbon sinks, offsetting carbon emissions (Gomiero et al. 2010). Therefore, Gomiero et al. claim that there is a clear limit to how “efficiently” arable land can be used and suggest that a precautionary approach should be adopted in removing plant material (and the nutrients contained therein) for fuel conversion.

Both the food versus fuel debate and the problem with using waste material for fuel stem from a broader question, namely, “What is the best possible use that these crops (this farmland) can be put to?” Compared to possible applications such as food, biopharming, and chemicals, biofuels are a low-value, low-priority application of biomass, given the high energy costs and huge quantities needed for fuel production, meaning that this question will rarely straightforwardly be answered with “biofuels.” Indeed, some companies that started developing algae-based biofuels have remained in business by switching to producing more profitable food supplements and chemicals (Biello 2011).

Land Use

Closely related to the food versus fuel debate is the issue of land use. The problem is basically that there is a finite amount of arable land to go around and land used to grow fuel crops cannot be used to grow food crops (though food and fuel crops can be combined, e.g., through intercropping or

planting fuel crops in hedges around food crop fields; also, crops like corn or soy can be sold either for food or for fuel). Thus, food can compete with fuel even though the fuel is made from nonfood crops.

One way to deal with this problem is to convert non-arable land (e.g., forest, savannah) into arable land. This land can then be used for food crops displaced by biofuel crops (which is called “indirect land use change” or ILUC, itself a problematic concept; see, e.g., Gamborg et al. 2011; NCB 2011, pp. 31–33). Another option is to use this land for the biofuel crops themselves (“direct land use change”), thus adding to the total amount of arable land. Not only can this be detrimental to local ecosystems and biodiversity, however, land conversion can also release great amounts of carbon into the atmosphere, essentially offsetting the emission gain of biofuels for tens or even hundreds of years (Gomiero et al. 2010).

Another way to deal with the problem of land availability is to grow fuel crops on non-arable land directly. It has been promised that second-generation biofuel crops can grow on marginal land that is otherwise unsuitable for growing food crops. However, it is generally the case that biofuel crops grow *better* on arable than on marginal land, giving farmers and businesses a strong incentive to plant their fuel crops on arable land. To this can be added the fact that marginal land, being marginal, generally has little or no infrastructure and is only sparsely populated, which raises the costs of planting, harvesting, and transport. An additional conceptual problem is that “marginal land” and “wasteland” are ill-defined terms (Guariguata et al. 2011), and land that is designated “marginal,” and thus fair target for acquisition by biofuel companies, may be home to poor subsistence farmers and endangered flora and fauna and otherwise provide valuable resources for local communities. Indeed, the designation of land as “wasteland” and the fact that local inhabitants often only have customary rather than legal land rights have repeatedly led to land grabbing by large corporations and forced eviction of its users (e.g., Kumar et al. 2012).

Global Biofuel Trade: Opportunities and Threats

Biofuel production and use practices have become increasingly globalized (Mol 2007): while the United States produces most of its own corn ethanol, the EU imports a sizeable amount of its biofuels from (sub)tropical countries, e.g., palm oil from Malaysia and Indonesia. There are several reasons for this. First, those countries have potentially more arable land available than the already intensively farmed EU. Second, some biofuel crops such as oil palm and *Jatropha* only grow in a (sub)tropical climate. Third, ideally, the global biofuel trade could boost developing countries' economies as well as the economic situation of their poor farmers, especially if processing and refining would also take place locally (Mol 2007). The global biofuel trade, however, gives rise to its own ethical issues.

The crucial responsibility for importing countries is to make sure that the costs of biofuel production (e.g., exploitation of local workers and the local environment) do not outweigh its benefits (e.g., reduced carbon emissions and increased energy security). Especially for first-generation biofuels, the drive for global sustainability and ambitious biofuel targets has often diminished what Mol (2007) calls "local sustainabilities" by way of deforestation, exploitation of workers, land grabbing, etc. According to Smith (2010), the global biofuel trade has involved the transfer of risks to the Global South and especially its poor, such as environmental and new market risks. This has led various organizations such as the NCB (2011) to propose criteria for sustainable biofuel production; it has also been suggested that a wide reflective equilibrium process should be used in order to achieve a fair biofuel policy (Jordaan 2007). Yet while criteria setting and certification (such as Fairtrade) are generally regarded favorably, some issues remain overlooked (Guariguata et al. 2011) or unanswered (Partzsch 2011) by it. For example, power inequalities among stakeholders or underrepresentation of stakeholders in developing countries can bias the criteria-setting process. In addition, there is a discussion on whether to adopt a global certification system, which would facilitate global trade and implementation or to adopt local frameworks that

could be better tailored to local situations (Guariguata et al. 2011).

Ethical Frameworks: Toward a Systematic Ethics of Biofuels

This section analyzes the relation between ethics of biofuels and broader trends within environmental and agricultural ethics. It has been noted that biofuels have often been discussed in a piecemeal way, lacking systematic ethical analysis (Buyx and Tait 2011). However at the same time several researchers have tried to integrate the debate about biofuels into broader ethical frameworks. One can distinguish approaches that focus on the value of nature (section "Biofuels and the Value of Nature") from those that focus on sociopolitical aspects of biofuels (section "The Politics of Biofuels"). Finally, this entry discusses first attempts to develop an overarching framework based on (a combination of) ethical principles and material values (section "General Ethical Principles and Biofuels").

Biofuels and the Value of Nature

The debate on biofuels can be placed in the broader debate about the role of nature in industrialized societies. Early environmental ethics argues that most ethical systems are anthropocentric (i.e., centered on the needs and values of humans) and that these systems therefore tend to ignore the value of nature. What is needed is, however, an ethics of responsibility in which nature is central. This implies reevaluating the values of nature, the role of wilderness or "untouched nature," the appropriate treatment of nature in agriculture (Thompson 1994), and the ethical status of plants and plant life integrity (Pouteau 2012). Ever since Heidegger's influential essay on technology, philosophers complain about the tendency to regard nature as a mere resource for human needs and describe countervisions of living in harmony with nature, or analyze ways to treat the land with respect, as an end in itself (Jasanoff 2010).

Thompson has pointed out that public views on farming contain an interesting tension: on the one side farming is a primal form of technology, "yet the farm is, for many, a paradigm of nature" (2009, p. 1257). Agriculture makes thus the

distinction between nature and culture more difficult, as plants and human coevolve and as farming is one of the oldest cultural techniques. As Karafyllis (2003) observes, the reputation of biofuels in the public debates benefits from the image of renewables as being part of the organic cycle of nature and thus exhibiting the “aura of naturalness.” This is in striking contrast to the role biotechnology and genetic modification plays in current and expected future production of biofuels. Karafyllis thus argues that also the acceptance of biotechnology should be included in technology assessment reports of biofuels.

The Politics of Biofuels

Recently the debate about biofuels has been put in the context of the classical debate between *technological determinism* and *social constructivism*. It has been argued that generally speaking engineers tend to embrace technological determinism, while researchers from a social science background often lean toward a social constructivist perspective. While technological determinism sees technology as bringing about societal changes, social constructivism rather sees society as bringing about technological changes. Biofuels can then be seen as an attempt to find a technological solution – a “techno-fix” – to a societal problem, being “therefore a classic example of engineers explicitly pushing for societal change” (Landeweerd et al. 2009, p. 539). A social constructivist perspective would, however, point out that not only a change in technology is needed but first and foremost also a social reorientation of our lifestyle. There seems to be a consensus that a middle ground between determinism and constructivism should be sought, even though there is disagreement as to what this middle position would be (Boucher 2011). Most authors in the debate highlight that it is therefore important to become aware of the underlying values of policy decisions in the field of biofuels (see also section “Global Biofuel Trade: Opportunities and Threats”).

As such, it has been suggested that global biofuel policy is subject to two different types of questions: (a) *whether* it should encourage biofuel production at all (b) and, *if* so, by which means it should reach this aim (Ng et al. 2010). Even if

biofuels help reducing GHG emissions, one could ask whether climate policy should be technology neutral. Economic support for biofuels might redirect investment away from other competing alternatives; therefore non-favoring approaches such as a carbon tax system might be more desirable. Assuming policy should favor biofuels, one can debate which means are most efficient to foster their production and usage. Wiesenthal et al. (2009) have compared tax reduction measures and legal obligations to fuel producers to blend conventional fuels with biofuels. While the consumer will not be burdened in the case of tax exemption, there will at the same time be loss of tax revenue for the state; obligations to fuel providers on the other hand are more far-reaching instruments that require public acceptance.

General Ethical Principles and Biofuels

Next to debates that link biofuels to environmental ethics or ethics of agriculture (section “[Biofuels and the Value of Nature](#)”), researchers have suggested to use classical ethical frameworks to investigate moral aspects of biofuels. Gamborg et al. (2011) contrast deontological and consequentialist perspectives. The latter focuses on costs and benefits and tries to evaluate potential risks, such as environmental degradation or higher food prices. Deontologists will also try to account for the intentions of the actors and stakeholders, which complicates the ethical evaluation, as it is not clear whose intentions to take into account, how to distinguish collective from individual intentions, and how to account for unintended consequences.

Next to these two classical ethical perspectives, philosophers from various traditions have investigated ethical issues of biofuels in the light of different moral and social traditions. These approaches include religious perspectives (Rasmussen et al. 2011), reflections on intercultural difference (e.g., Landeweerd et al. 2012), or gender aspects (Rometsch 2012). The most comprehensive ethical evaluation thus far has been presented by the NCB (2011). The authors suggest evaluating biofuels in light of humans, nature, and society: biofuel production should be in line with (1) human rights and (2) environmental sustainability and achieve

substantial GHG reduction (3). Principles 4 and 5 address socioeconomic issues such as just rewards (4) and an equitable distribution of costs and benefits (5). The authors conclude that there is an ethical duty to develop biofuels, but only if these principles are met.

Conclusion

Although there is much to criticize about biofuels, the conclusion should not be drawn that there is no future for them. Indeed, the oil consumption-related problems which biofuels were supposed to relieve still stand, and while large-scale production and use of biofuels has often led to large-scale problems, this does not mean that there cannot be local niches for production and use. Nor does it mean that there should be no further research on biofuels, whether or not this is considered an ethical duty. Indeed, many open questions with regard to biofuels would benefit from attention from scientists of all kinds, including the social sciences and the humanities, as the Ethical Frameworks section has shown. It does mean, however, that biofuel production and policy setting should proceed with caution. Clearly, its effects on food security, land use, and local communities and ecosystems should be carefully monitored, lest the cure (again) be worse than the disease.

Summary

Biofuels have gained much attention in the last decades as a supposedly sustainable alternative for fossil fuels. However, their production has been accompanied by numerous ethical problems. This entry presents an overview of those problems. First, it explains what biofuels are. Next, it goes into practical issues such as the food versus fuel trade-off, problems with land use for biofuels, and social consequences of the global biofuel trade. Finally, it gives an overview of different ethical frameworks that have been used to evaluate biofuels, including frameworks explicating the value of nature; political and social aspects of biofuels; and classical ethical frameworks.

Introduction

Biopharming is the production and use of transgenic plants and animals genetically engineered to produce pharmaceutical substances for use in humans or animals. It often involves the insertion of gene constructs derived from humans. Biopharming exists on a spectrum of activity and is not clearly demarcated from its nearest neighbors. For example, genetically modified yeast, bacteria, and animal cell cultures have for some time been used to produce pharmaceutical substances in enclosed bioreactor systems, but are generally not included in the definition of

biopharming. On the other hand, plant cell cultures, a newer development but also involving enclosed bioreactors, are typically included together with whole-plant methods in plant biopharming. While animals are also being genetically modified to alter their nutritional composition, to make them better models for human disease, and to provide more compatible organs for transplantation into humans, these are typically excluded from the definition of biopharming.

There has been little scholarly discussion of biopharming from an ethical perspective; two exceptions are Birnbacher (2007) and Reh binder et al. (2009). Animal biopharming typically receives brief mention in analyses of the ethics of genetically modifying animals, although public debate and controversy around biopharm animals have attracted some scholarly attention (Taussig 2004; Väliverronen 2004). Plant biopharming is often assumed not to raise specifically ethical issues, although some attention has been given public views of the technology and its use (e.g., Einseidel and Medlock 2005; Milne 2010). This entry examines important ethical issues in animal and plant biopharming, focusing particularly on the exaggeration of benefits, the potential for harm, and the (in)adequacy of regulatory oversight, among other issues.

Background

The pharmaceutical compounds intended to be produced through biopharming are a subset of the class of pharmaceuticals known as biopharmaceuticals. Biopharmaceuticals are medicinal drugs derived from living organisms and requiring biotechnological intervention; they are distinguished from those produced through chemical synthesis or by direct extraction from a native (non-engineered) biological source. They are typically manufactured using microorganisms and cell cultures in indoor facilities. Biopharming is thus an alternative method for the production of biopharmaceuticals.

Biopharming has been carried out experimentally for more than 20 years. As of this writing,

three biopharming-produced pharmaceuticals have been approved for use in humans in the USA and/or EU (produced in transgenic goats, transgenic rabbits, and transgenic carrot cell cultures). A number of others, using both plants and animals, are in clinical trials. A very wide range of plants and animals are used as biopharming production “platforms” or “living bioreactors.”

Biopharming has not been widely discussed in the popular media, even though it has been implicated in several genetic-modification controversies. The animal who became known as Stier Herman (Herman the Bull), the first transgenic bovine, was a biopharm animal produced in the Netherlands in 1990 and modified with the human gene for producing lactoferrin. The subject of great controversy, he was created in the hope that he would confer on his female offspring the capacity to produce recombinant human lactoferrin in their milk. The company that created him, Gene Pharming Europe, declared that Herman and his offspring were being produced solely for biomedical research purposes. This was permitted under Dutch legislation that allowed the genetic modification of animals only in exceptional circumstances, one of which was supplying products for medical use in humans that could not otherwise be supplied. The controversy escalated when it was discovered that the research had been funded by a company that intended to use the lactoferrin in baby formula (Taussig 2004).

In 2002, US government inspectors found that ProdiGene had failed to comply with protocols for field trialing corn genetically modified to produce an experimental pig vaccine. As a result, “volunteer” plants sprouted the following season, when soybeans were grown on the site, and were not removed, enabling them to contaminate the commercial cornfields that surrounded the experimental plot. In a second location, where the same thing had occurred, ProdiGene was found to have harvested the soybeans together with the volunteer biopharm corn, despite assuring the regulator that it had destroyed the corn plants prior to harvesting. Despite having been levied a very hefty fine for this, and agreeing to a new compliance program and audit requirements, ProdiGene was found to have violated protocols again in

2004, failing to monitor for volunteer plants from a field trial of biopharm corn. Volunteer corn plants were found by government inspectors growing and flowering within the fallow zone surrounding the field trial and in a nearby sorghum field. They also found that oats growing in the border rows immediately surrounding the biopharm corn had been harvested, contrary to requirements (APHIS n.d.). Partly as a result of these incidents, actors ranging from the Union of Concerned Scientists through the Grocery Manufacturers of America to the Editors of *Nature Biotechnology* called for the exclusion of food crops from biopharming.

The Promise and Promotion of Biopharming

In the 1990s and early 2000s, biopharming's promoters painted a picture of dairy farmers sending their milk off to the drug company and crop farmers growing large quantities of therapeutic proteins as easily as they grow wheat, corn, or soybeans. In the public sphere, biopharming has been described as a way to produce new treatments for human diseases, to reduce the cost of drugs to consumers, to improve the economic viability of farming and rural regions, and to increase developing countries' access to medicines. On the last point, the idea of the edible vaccine was given prominence: food plants such as bananas would be engineered to contain the vaccine in their fruit, which would obviate the need for the temperature-controlled, hygienic conditions required by conventional injectable vaccines. To potential investors, biopharming has been promoted as a method able to outcompete conventional production methods, based on the notion that agricultural practices and infrastructure are less costly and more easily upscaled or downscaled than the kinds of production facilities required by microorganism and cell culture production.

As has become typical of biotechnological innovation (Brown 2003), this promotion of biopharming was characterized by what could be called "hype." Early claims and promises were not

well grounded in reality and far outstripped actual achievements. Although the original promises can still be found in some pronouncements about biopharming and in debate around its regulation, expectations for the technology appear to have shifted considerably over the past 10 years.

The need to protect the quality and purity of pharmaceutical substances from environmental contamination and to protect the environment from pharmaceutical contamination casts serious doubt on the adequacy and acceptability of utilizing existing agricultural practices and infrastructure for drug production. Much research on plant biopharming now focuses on "indoor" versions, using plant cells, algae, or duckweed grown in full containment. The biopharm goats that produce the drug ATryn are kept in dedicated indoor production facilities owned and run by the biotechnology company that developed them – a far cry from the dairy farmer's "pharma herd." The excitement over edible vaccines has also ebbed, as problems of quality and dose control become apparent. It is now widely accepted that while vaccines may be produced in plants, they will need extraction and some degree of processing before they can be administered, whether orally or through injection (Rybicki 2010).

The business case for biopharming has also run into difficulties. Production costs are a very small part of overall drug costs, and pharmaceutical companies have not been eager to take on the risks of the new production method in the hope of economizing on what is already a relatively minor cost. Drug prices are brought down, in general, not by lowering production costs but by loss of patent protection and the introduction of competition. Production costs would be more relevant for the biopharmaceutical equivalent of generic drugs, so-called biosimilars, but these face much greater challenges than chemically synthesized drugs when it comes to demonstrating their equivalence to the original patented product. In addition, the biopharming process is much more difficult to set up than the production of generic chemically synthesized drugs; it therefore seems that biopharmaceutical producers are less likely to attract competitive generic producers. Meanwhile, conventional VAT bioreactor

technology has not stood still, with developments improving productivity, scalability, and cost-efficiency.

Nonetheless, all types of biopharming still have their promoters, and research is still being pursued by competing groups using a range of animals (large and small), outdoor plant production, indoor plant production, and plant cell cultures. The proponents of each argue that their platform has advantages in productivity, scalability, speed of response, safety of drug produced, cost, or suitability to particular conditions. A significant amount of this research is publicly funded.

Animal Biopharming

Considerably less attention, both public and scholarly, has been paid to biopharm animals than to transgenic animals intended for food or as organ donors to humans (xenotransplantation). As biopharm animals are a subset of transgenic animals, however, they raise many of the same questions: for example, does biopharming inflict suffering on the animals? Can this suffering be justified? What does such intensified instrumentalization mean for humans' relationship with animals and humans' understanding of themselves? Is it foolhardy, or hubristic, to intervene in complex systems about which we have limited understanding?

Many biopharm animals are currently created through cloning, with implantation into another animal for gestation. Most cloned embryos fail to develop to term, and of live births, many suffer from crippling or fatal abnormalities, the causes of which are not understood. Gestating animals also suffer health problems: for example, bovine gestators of cloned animals are much more than normally prone to dystocia due to oversized calves ("large calf syndrome") and to hydroallantois, caused by a defective placenta; both of these cause pain and suffering and can be fatal.

Cloned animals are more prone to musculoskeletal abnormalities and, perhaps particularly significant for biopharming, compromised

immune systems. Abnormalities may not reveal themselves before the animal enters a production system, while some epigenetic aberrations may not show themselves in any obvious phenotypical way (Laible and Wells 2007). Cloned animals can also pass on pathological abnormalities to their offspring.

Aberrant transgene integration and its effects are poorly understood. Further, according to Reh binder et al. (2009), "[s]tudies of welfare issues arising from making transgenic animals are still in their infancy" (p. 196). These and other unpredicted and undesirable results highlight for some the degree to which intervention outpaces understanding and for others the riskiness of the endeavor: How can nonobvious, unanticipated, and deleterious changes be identified in transgenic animals (or plants) if one does not know what to look for? And how can the risk of such outcomes be evaluated when understanding is so limited?

While these problems are associated with cloned transgenic animals in general, particular to biopharming is the problem of the effect on the animals of the bioactive pharmaceutical substance their cells have been engineered to produce in high concentrations. This would vary depending on the nature of the pharmaceutical substance and appears to be both a potential animal-welfare hazard and a limitation of animal biopharming (i.e., certain kinds of substances may not be producible in animals because of their deleterious effects on the animals producing them).

When it comes to assessing the acceptability of using animals in this way, the harms to the animals are often weighed against the potential benefits to humans of the drugs produced. However, it is also necessary to ask: are there alternatives? While it is sometimes claimed that animals could potentially be used to produce drugs whose particular characteristics make them difficult or impossible to produce in other ways, this is not the case for the uses to which biopharm animals are currently being put. The same drugs can be, and are being, produced through conventional biopharmaceutical production and/or through biopharm plants or plant cells. Whether or not one views the harms

suffered by biopharm animals to be justified may depend, at least if one takes a utilitarian or consequentialist approach, on how much faith one places in these claims to future indispensability.

There are fewer concerns about keeping biopharm products out of the food supply than in the case of plant biopharming, due to the fact that the relevant animals are easier to monitor than pollen or seeds. However, there has already been at least one case of possible inadvertent contamination of the food supply by animal biopharming. Between 2001 and 2003, the University of Illinois released 356 pigs, which were part of their transgenic biopharming experiments to produce certain proteins in the milk of sows, to livestock dealers. The university argued that the pigs did not contain the transgenes of their parent stock nor were they old enough to be lactating; however, investigations by the FDA found that records were inadequately kept and they were unable to verify this (FDA 2003).

As this incident suggests, biopharming operations will have an incentive to derive some value from animals or animal materials produced by the operation but not utilizable for biopharming – for example, offspring who do not exhibit the desired traits or are surplus to requirements. It is not unlikely, therefore, that biopharm operators will seek approval for excess animals to be permitted in human food or animal feed (U.S. National Research Council 2002). This would create pathways for potential contamination of the food supply through animal biopharming.

Risks of contamination of the environment and adverse impacts on other organisms appear to be lower than with biopharm plants because biopharm animals are easier to contain than, e.g., pollen from biopharm crops. However, outdoor animal biopharming (or careless management of indoor biopharming) could potentially impact on organisms in the environment such as soil microorganisms, animals and plants that feed on animal waste, and blood-sucking insects. Through horizontal gene transfer, biopharm animals producing antibiotic substances (or therapeutics with antimicrobial properties, a common trait of pharmaceutical substances not intended to be used as antibiotics) could potentially aggravate the

problem of antibiotic-resistant bacteria by encouraging resistance in populations of soil bacteria or bacteria that are the animal's natural commensals. The degree to which this may be a problem will depend, *inter alia*, on the substances produced and the scale and location of the biopharming operation.

A recognized concern is the possibility of passing on zoonotic diseases (diseases that can be transmitted from animals to humans) through drugs from biopharmed animals. These include prion diseases, that is, transmissible spongiform encephalopathies, including bovine spongiform encephalopathy (BSE), variant Creutzfeldt-Jakob disease (vCJD), and scrapie. The company producing ATryn sourced its original (non-GM) goats from New Zealand because that country has been declared scrapie-free. There is also a risk that the animals will contract zoonotic diseases through exposure to infected organisms in their environment. It is likely for this reason, rather than to prevent contamination of the environment, that the goats producing ATryn are kept in an indoor facility. Keeping animals in indoor facilities may, however, raise other animal-welfare issues, depending on the animals and conditions in which they are kept. While these conditions will almost certainly be more hygienic than those characterizing many food-animal operations, they may still, through confinement, prevent the animals from expressing their natural behaviors.

Plant Biopharming

Plant biopharming is argued to pose fewer risks to the recipient of the biopharmed drug than animal pharming, because plant diseases are generally not seen as a threat to human health. While plant-biopharmed drugs cannot pass on zoonotic diseases, they potentially pose greater allergenicity and immunogenicity problems, due, in simple terms, to differences between plants and animals in protein production processes (i.e., in the “post-translational modifications” that occur after the RNA has been translated into protein). Much research in this field aims at making the

therapeutic proteins produced by biopharm plants more human-friendly.

All biopharmaceuticals require extraction and purification. While a challenge for animal biopharming is the detection and removal of zoonotic disease, for outdoor plant biopharming, the purification process must be able to remove assorted environmental contaminants in and on the plant material, such as pesticide residues (including from pesticide drift), insect parts, bird feces, etc. This would presumably warrant changes to existing purification processes and protocols.

A major concern associated with plant biopharming is the possibility of the unintentional contamination of food with bioactive pharmaceutical substances. Some developers are focusing on nonfood plants, such as tobacco, or on plant cell cultures, algae, or duckweed, but a large variety of food plants continue to be used as bioreactors, including major food crops, such as rice, maize, and potatoes. Those who use food plants, especially major food crops, argue that this is justified by the fact that more is known about their physiology, agricultural needs, and protein-expression mechanisms (Sparrow et al. 2007).

Contamination can occur through a number of pathways, including cross-pollination with non-biopharm crops, seed dispersal, the germination of residual seed, postharvest mishandling (e.g., commingling in storage), the use of agricultural and transport machinery on both biopharm and non-biopharm crops, and the inappropriate disposal of biopharm crop waste. The risk of contamination is obviously increased when food crops (or nonfood crops used in processed foods, such as cotton) are used as bioreactors and open-air production methods are used. While a number of technical measures and production protocols have been proposed for these situations, it is acknowledged that even with these measures in place, the risk of contamination cannot be eliminated entirely.

Open-air plant biopharming also appears to pose, at least potentially, significant risks to other organisms in its environment. Birds, insects, rodents, and other animals may feed on parts of the plant producing the pharmaceutical substance. In addition, farmworkers (and close neighbors)

may be adversely impacted through inhalation of pollen containing pharmaceutical substances. Soil microorganisms will also come into contact with biopharm plants. As with biopharm animals, biopharm plants producing antibiotic substances (or therapeutics with antimicrobial properties) may exacerbate problems of antibiotic resistance.

Regulation

Regulatory frameworks for biopharming have been slow to develop and have lagged well behind the development and application of the technology itself. This applies both to the production and handling of biopharm plants and animals and to the production of drugs derived from them (Rehbinder et al. 2009; Fischer et al. 2012). What might be called the liminality of biopharm plants and animals poses challenges for regulation. For example, agriculture and medicines are typically subject to different governance regimes, yet biopharm plants and animals belong to both categories (or to neither). Different regulatory agencies may have different cultures and be embedded in different power relations, which can pose problems for effective cooperation.

Biopharming activity is generally being governed through regulatory frameworks developed for other purposes, and this can result in regulatory gaps and poor fit. The development of biopharm plants has occurred in North America and Europe within regulatory frameworks designed for so-called first-generation GM food and fiber crops (e.g., those intended to produce Bt toxin or to be herbicide-tolerant); this appears likely to continue (APHIS 2008; EFSA 2009). While these frameworks may enable characteristics specific to biopharm plants to be considered in, for example, a case-by-case risk assessment, their use may still entail the importation of inappropriate assumptions into biopharming regulation (Goven and Morris 2012). These frameworks rely heavily on their established approaches to risk assessment and risk management; Rehbinder et al. (2009, p. 196) argue that biopharm plants and animals differ sufficiently from other GMOs to pose new, as-yet unidentified

risks, raising difficulties for the identification of hazards and for the evaluation of their likelihood within these frameworks.

Protecting the welfare of biopharm animals may also encounter category problems. For example, some jurisdictions distinguish between experimental animal trials and the use of animals in production. Biopharm animals do not unambiguously fit either category: the distinction between animal trials to produce new knowledge, on the one hand, and breeding and production activities, on the other, is in their case not clear-cut. Moreover, many of the welfare problems associated with biopharming result from experimentation on embryos rather than the animals themselves, thus possibly falling outside the regulation of animal trials. This misfit is at least partly a result of legislation on animal trials generally having been developed with the safety testing of chemicals in mind. Biopharming animals may also fall outside the protections extended to farm animals, because they do not serve agricultural purposes. (On these issues, see Müller-Terpitz 2007; Reh binder et al. 2009, Chap. 8). In another example of categorical difficulty, the USA in 2008 decided that biopharm animals themselves would be regulated as drugs (specifically, “new animal drugs”).

Regulation of drugs produced through biopharming was also adapted rather than purpose-built. Good Manufacturing Practice (GMP) guidelines for biopharm drugs were originally modeled on those for animal cell cultures. These, however, are seen as too restrictive by those working with whole plants (rather than plant cells); established guidelines on the removal of contaminants in production from cell cultures, for example, provide immediate challenges for outdoor-biopharmed plants, as types of likely and possible contaminants differ significantly from those found in cell culture production, as do methods for their removal. Standards for containment, hygiene, and batch-to-batch consistency developed for animal cell production cannot be met by outdoor biopharm plant production, whose proponents have instead argued for a different approach, one which “borrow[s] much from the concepts already in place for genetically modified food crops” (Fischer et al. 2012, p. 437). Current

guidelines in the EU and USA indicate that regulators are shying away from specifying in advance the kinds of production processes that are acceptable (in terms of, e.g., organism used or degree of containment) and instead will decide on a case-by-case basis whether to accept drugs produced through different platforms.

Overarching Ethical Issues

Hype and Its Ethical Effects

Inflated benefit claims, both financial and humanitarian, are seen as characteristic of biotechnology (Brown 2003) and have featured in the promotion of biopharming (Välvirronen 2004; Milne 2010, 2012; Bloomfield and Doolin 2011). Scholarship within the subfield known as the sociology of expectations (see Borup et al. 2006 for an overview) has emphasized the key role played by the creation of expectations of future achievements in mobilizing support for technoscience. Claims of expected benefits can influence not only investment (including public investment) but also regulatory decisions. Although not uniquely, the history of biopharming raises questions about the ethics of promoting new technoscience through poorly grounded claims. As Brown (2003) has argued in relation to xenotransplantation research, unrealistic benefit claims may be weighed up against harms such that, for example, a degree of animal suffering is permitted that would not otherwise be. This suggests that humanitarian claims (e.g., that biopharming will enable the development of therapeutics for currently untreatable diseases or that it will provide safe, low-cost medicine to developing countries) should receive greater scrutiny. It also suggests that the ethics of making such claims be considered. The reliability of benefit claims is also crucial to our consideration of whether it would be ethical *not* to pursue biopharming in any or all of its forms.

Inflicting and Exposing to Harm

As indicated above, the cloning of biopharm animals inflicts pain and suffering on (some) animals. The actions of the biopharmed substance within the body of the animal can also cause harm.

Protecting the biopharmaceutical from contamination may require housing the biopharm animals in a controlled, indoor environment, which could include isolation of individual animals from each other (to prevent the spread of infectious disease). Some would argue that, at least for some animal species, this in itself would inflict harm.

Biopharming has the potential to expose a range of others to harm. Despite the efforts of drug regulators to prevent it, patients, and those in contact with them, may contract zoonotic diseases passed on through biopharm animals; patients may also be harmed by novel contaminants that have not been removed through purification processes. This may call for a discussion of whether patients should be informed of the sources of these drugs (Rehbinder et al. 2009). Open-air biopharming may also inflict harm on its wider environment, specifically on those organisms that come into contact with biopharm plants or animals or their residues. These may include humans, whether farmworkers or those who consume food that has been contaminated through open-air biopharming, and will certainly include other species. This would amount to a deliberate introduction of harm or potential harm where none existed before, and thus requires justification.

Weighing Costs and Benefits: The Role of Alternatives and Cost Savings

A common approach to the question of justification is to weigh harms and potential harms against benefits and potential benefits. This brings us back to the reliability of benefit claims but also to the question of alternatives. Biopharming is being pursued simultaneously across a wide range of “platforms.” Given this and the uncertainties that still characterize the technology, it would seem to be difficult to argue that there is no alternative to any one particular platform. Choice of platform appears to be driven by economic and intellectual-property considerations more than technical feasibility (Fischer et al. 2012). This substitutability is as relevant as potential benefits to ethical discussions of the acceptability of inflicting harm (on biopharm animals or other organisms) by the use of, e.g., animal biopharming or outdoor plant biopharming.

Because expectations of cost savings are such an important driver of biopharming, the problem of whether monetary benefits (through cost savings) can outweigh the infliction of harm is likely to arise. Cost savings must then be examined further: who will benefit? If cost savings simply add to corporate profits, is this sufficient benefit to outweigh, e.g., the infliction of suffering on animals or of added risk on human populations? How can we know in advance how cost savings will be distributed, if they do eventuate?

Regulatory Values

As noted, biopharming regulations have largely been derived from existing regulations developed for other purposes. Regulatory approaches institutionalize priorities and so embody values. For example, outdoor plant biopharming has largely been assimilated into regulatory regimes for other types of GM plants. These frameworks place a high priority on producer freedom of choice and market-driven innovation for economic competitiveness. This is reflected in the fact that an economic actor’s desire to develop, use, or buy a technology is in itself taken as evidence of benefit; no further benefit need be demonstrated. This does not appear to allow the kind of ethical querying of the nature and distribution of benefit, or consideration of the existence of alternatives, discussed above (Goven and Morris 2012).

Hubris, Irresponsibility, and Wisdom

Like other technological interventions characterized by a large degree of both uncertainty and ignorance and a potential to inflict irreversible damage on individuals and ecosystems, biopharming, or at least some of its forms, might be considered to embody a hubristic and irresponsible meddling with life (Fiester 2008). Biopharming (also not uniquely) may raise concerns that we do it “because we can” rather than because it is necessary or wise. This in turn raises questions about the ethics of our technoscientific system and its regulation. Where in the process is there an opportunity to ask “Is it wise? Should we do it at all?” rather than “How can we minimize its risks without discouraging its development?”

Summary

Biopharming involves genetically engineering plants and animals, typically with human gene constructs, to produce biopharmaceuticals. It has thus far received little attention within bioethics or among social scientists. The nature and scope of the potential opportunities represented by biopharming remain unclear. The potential hazards associated with biopharming are wide-ranging and vary according to the “platform” used. Regulation of biopharming has not kept up with technological development and is arguably under-specified. Biopharming raises ethical issues in relation to the performative effects of inflated benefit claims, the infliction of harm and potential harm on biopharm animals and other organisms (including humans), the opportunity to consider alternatives and the significance and distribution of cost savings when evaluating biopharming’s acceptability, the values embedded in regulatory frameworks, and the proper response to uncertainty regarding far-reaching effects.

Agroterrorism; Biosafety bioterrorism;
Biosecurity; Food quality; Food safety

Introduction

Securing food systems against deliberate attack from malevolent actors is perhaps an overlooked issue in discussions of ethics of food and agriculture. This entry raises biosecurity of food systems as an issue of ethical importance, with the aim of showing how biosecurity, understood in a national security context, is relevant to discussions of food ethics and philosophy. A basic point of this entry is that deliberate attacks on food systems have the

potential to cause widespread harm to people and severe economic damage to food systems. Biosecurity is understood in this entry as having a focus on deliberate acts of harm. Understanding biosecurity of food systems in this manner does not garner typical discussion in food and agriculture studies. A partial explanation for this is multiple contrasting meanings of similar terms like food security, food safety, food biosecurity, biosecurity, and biosafety. Given the potential high impact of a deliberate attack on a food system, this entry will present biosecurity of food systems as an issue of importance, and one that needs to be understood alongside discussions of food security and food biosecurity, more generally construed.

The entry shows that biosecurity, understood with reference to deliberate harms, is an important ethical issue. Following a brief background discussion, the entry gives a general overview of relevant terms. Modeling of an act of agricultural terrorism, the deliberate poisoning of a food supply with botulinum toxin as with potentially devastating results, is used to show the high impact of an attack on a food system. In order to explain this high impact, common features of modern integrated food systems such as collection, centralization, and combination of food products are raised as making food systems vulnerable targets of attack. Finally, food traceability and response systems are raised as necessary elements in reducing vulnerability and limiting impacts.

Background

For the majority of people in the developed world, perhaps uniquely in human history, a relatively high proportion of the population typically do not worry about where their food is coming from: the supply of food is assumed to be reliable (Thompson 2010, p. 6). Such confidence applies not only to people’s ability to reliably *access* cheap food and in large amounts, but also that people can generally feel that the *quality* of food itself is assured: people do not typically worry whether their food will make them seriously ill. This entry focuses on the latter point, an assumed

safety of food products. This entry looks at the problem of people deliberately targeting the food system for attack.

Though food industrialization has certainly increased the likelihood of food safety – a perception of total safety of food processes is contestable. Eric Schlosser writes that the “industrialized and centralized system of food processing has created a whole new sort of outbreak, one that can potentially sicken millions of people” (Schlosser 2003, p. 195). Aspects of the food production system have the potential to place many people at risk of illness from consuming contaminated food products. Paul Roberts states “[T]here are also undeniable parallels between these shifts in food-borne disease – the kinds of pathogens circulating, the patterns of outbreaks and the difficulty in treatment – and the emergence of a food system geared toward high volume, low costs, and rapid, worldwide distribution” (Roberts 2008, p. 178). The integrity of food supply chains can be lost through the actions of agents at key points in a food supply chain. Consider, for example, the “European horsemeat scandal” of 2012–2013, in which horsemeat was found in European beef products (Traynor et al. 2013). Inputs to food supply chains are not always assured. This is something that can be exploited not only by negligence or personal gain but also through the deliberate actions of malicious actors.

Food-borne diseases are typically covered in relation to food safety. However, when considering things from a point of national security, food production systems present targets for malicious actors to disrupt and perhaps harm large sectors of society. Modern food systems frequently collect inputs from a wide range of producers and sources, mix these inputs together in centralized processes, and then distribute widely to a large number of consumers locally, nationally, and increasingly internationally (Schlosser 2003, pp. 225–252). It is this model of collection, concentration, combination, and distribution that makes food processes a potential target for malicious actors. As with events of accidental food-borne illness, if a malicious actor was to get certain toxins into a food supply chain at key

steps in the process, this could result in an outbreak of illness, causing public fear and death.

Food Security, Food Safety, and Biosecurity

The focus of this entry, biosecurity and food systems, imports a model of food biosecurity from a national security vocabulary that may be outside typical discussions in agriculture and food science. Given the nonstandard usage, a general overview of key terms and their multiple uses is presented here. The particular intended meaning of biosecurity and food systems as a national security concern is explained.

Firstly, a distinction must be made between food security and food safety. Food security can be understood as a political/economic concept. With reference to the aims of global actors such as the United Nations (UN), the World Bank, and the Food and Agriculture Organization (FAO), food security “should be envisioned as a project of economic and developmental globalization that is designed to help poor and underdeveloped countries. . . [and focuses] on how growth will be most beneficial to the global poor” (Schanbacher 2010, p. 3). The typical concern is with “the just and fair supply of food to human beings” (Coff et al. 2008, p. 8). With concepts such as globalization and poverty underpinning the motivations and methods of groups like the FAO, food security for the world’s poor is something to be achieved through economic programs (Schanbacher 2010, pp. 2–23). While individual health and survival are chief concerns of food security, the problem is, roughly, one of creation and distribution of resources, and so the discussions are primarily in areas of political philosophy, economic theory, trade, and the like. This is discussed in more detail in the food security entry in this encyclopedia.

Contrast this model of food security with food safety: “Food safety deals with the safety of the food: food should not endanger the health of consumers due to pathogens or pollution present in the food. There are ongoing discussions about what is safe enough and whose definition of safety should be followed” (Coff et al. 2008, p. 8).

Rather than creating and distributing enough food resources for people, particularly the world's poor, food safety is about ensuring that the food that people consume will not harm them. In what follows, I look into three different ways of conceptualizing biosecurity.

In contrast to food security and fitting under the umbrella of food safety, food *bio*security is often concerned with ways to keep agricultural systems and/or food productions systems free from pests and diseases. A first focus of food biosecurity within agricultural systems is the protection of production/producers from pests and other diseases and ways of limiting the impact of such pests. Ronald Atlas, the former president of the American Society for Microbiology and co-director of the Center for Health Hazards Preparedness at the University of Louisville, writes: "New Zealand, for example, published in August 2003 a biosecurity strategy aimed at economic, environmental, and health protection from pests and diseases. . . In this case biosecurity means trying to prevent new pests and diseases arriving and eradicating or controlling those already present" (Atlas 2005, p. 122).

A second understanding of food biosecurity is concerned with the defensive measures to be used and developed against agents that pose biological risk following consumption of the food: "The primary goal of biosecurity is to protect against the risk posed by disease and organisms; the primary tools of biosecurity are exclusion, eradication, and control, supported by expert system management, practical protocols, and the rapid and efficient securing and sharing of vital information. Biosecurity is therefore the sum of risk management practices in defense against biological threats" (National Association of State Departments of Agriculture 2001). The key difference between the first and second conceptualization is that the first conceptualization is primarily focused on risks to *producers*, while the second is focused on risks to *consumers*.

A third way of conceiving food biosecurity is in reference to *deliberate* attacks on the food supply, with attacks having intent to disrupt or harm society. For instance, the Biosafety in Microbiological and Biomedical Laboratories

(BMBL) Manual 3 defines biosecurity as "the protection of high-consequence microbial agents and toxins, or critical relevant information, against theft or diversion *by those who intend to pursue intentional misuse*" (Atlas 2005, p. 122, emphasis mine). Rather than conceiving food biosecurity by reference to the concerns of environment or agriculture, broadly construed, some discussions of food biosecurity focus instead on food production as a national security concern. In the context of national security measures, biosecurity means protecting biological resources against acquisition by terrorists.

Given these multiple conceptions around security and food, food security, food safety, and food biosafety, their use typically varies upon on the given area of discussion. That is, those concerned with equal distribution of resources are most likely to use references to food security, and those concerned with issues of quarantine and defense against pests are likely to consider references along the lines of food safety, while those interested in national security and protection against deliberate malicious use are most likely to be interested in food biosecurity.

On this third conceptualization, food biosecurity is concerned with acts of terrorism, warfare, or other malicious intent, which seek to disrupt and/or harm society and individuals through deliberate addition of toxic and/or disease causing agents into the food production system. It is this particular conceptualization that will be the focus for the remainder of the entry. Wherever convenient, however, in order to make the national security focus distinct from standard discussions in agriculture, the entry will refer to biosecurity of food systems, rather than food biosecurity.

Bioterrorism and Food Systems

The reason for a focus on biosecurity of food systems is that toxins and pathogens in food systems can cause massive social disruption and can potentially harm or kill large numbers of people. The initial claim is that food and food supply chains are potential targets of bioterrorist activity. Coupling

the potential lethality of certain food toxins and pathogens with the broad distribution from centralized processing points means that aspects of the food industry offer potential ways to “weaponize” food and/or its food delivery systems. Some claim that using food as a delivery method could produce the highest number of casualties of any bioterrorist act (W. Seth Carus, quoted in Von Bredow et al. 1999, p. 169).

An initial point to cover is if there is actually cause for concern about attacks on food systems. Seven days after the World Trade Center attacks of September 11, 2001, there was bioterrorist attack using anthrax spores that killed five people and infected another seventeen (N.P.R. 2011). While few deaths occurred, the so-called “Amerithrax” attack raised the specter of deliberate use of harmful microbial agents. In terms of targeting food systems, while the number of deliberate attacks on food systems is extremely low, there is at least one known bioterrorism attack on a food system. As described in the chapter “Influencing An Election: America’s First Modern Bioterrorist Attack” (McCann 2006, pp. 151–158), a group following the “guru” Bhagwan Shree Rajneesh attempted to change the outcome of a local election in the US town of Dalles in the state of Oregon. Starting on August 29, 1984, two city officials were intentionally poisoned with *Salmonella typhimurium*. Following this, 751 people were poisoned by *Salmonella*, intentionally placed in salad bars in ten Dalles restaurants. The ultimate aim of the attacks was to make enough people sick that such that their votes in the local election would bring about the culprit’s desired outcome. What the Amerithrax and Dalles examples show is that there are people with the motive to harm using biological agents, and there is proof of concept – food systems have been targeted.

In their discussion of potential tools of bioterrorism, Seumas Miller and Michael Selgelid discuss research programs that may confer resistance to antibiotic or antiviral agents, enhance pathogen virulence, increase the transmissibility of a pathogen, alter a pathogen’s host range, and enable the weaponization of a biological agent or toxin (Miller and Selgelid 2008, pp. 19–26). Food systems present a potential delivery system for

bioweapons and as such figure in an analysis of potential tools of bioterrorism.

Taking the threat of bioterrorism seriously, Lawrence Wein and Yifan Liu sought to predict the results of a deliberate poisoning of a milk supply equivalent to California with botulinum toxin. Botulinum toxin is not a standard food biosecurity concern. However, on Wein and Liu’s analysis, if left undetected, 1 g of the toxin could cause around 100,000 casualties, and 10 g could cause up to 568,000 casualties (Wein and Liu 2005, p. 9985). Furthermore, Wein and Liu’s modeling of botulinum in the milk supply “are applicable to similar food products, such as fruit and vegetable juices, canned foods. . . and perhaps grain based and other foods possessing the bow-tie-shaped supply chain” (Wein and Liu 2005, p. 9984). With such massive disruption and harm, food systems thus figure in national security discussions and are relevant to discussions of biosecurity.

Food System as Targets

Essential to the biosecurity concerns is the capacity for toxins in food to be rapidly and easily consumed by large numbers of people. Central to this are the methods of the industrial food process that allow toxins to be distributed to large numbers of people at a national and international level. In these systems, the food type (i.e., mince for hamburgers or dairy milk) is progressively concentrated into central processing plants, which then distribute the food product progressively out to more and more consumers. The key point here is what is called the “bow-tie-shaped supply chain” (Wein and Liu 2005, p. 9984), in which food supplies are concentrated and mixed at central processing points and then distributed out, forming a bow-tie-like shape.

The “bow-tie” model of food production refers to processes, whereby the initial food inputs are concentrated, centralized, and combined prior to broad dispersal. This bow-tie shape Schlosser argued (Schlosser 2003, pp. 195–197) was a key element in food-borne illnesses arising from consumption of hamburgers. A similar set of industrial processes have been implicated in the emerging information on the European horsemeat

example in which horsemeat was effectively mixed through large numbers of food products and then distributed widely (Traynor et al. 2013). The relevance of these examples of food illness and food quality is to show that the bow-tie processes present certain food systems as a potential point of terrorist attack. Wein and Liu's (Wein and Liu 2005) investigation showed that adding the botulinum toxin at key points in the food production system could have devastating impact.

Prevention of Bioterrorism: Food Traceability

In addition to problems of harm and food chain integrity are issues of national and international oversight. In one well-known example of food-borne illness, an *E. coli* O157:H7 outbreak in 1992 killed four and sickened 600 people (Roberts 2008, p. 182). Another outbreak of *E. coli* strain O104:H4 in Europe in 2011 had 3816 reported cases and included 54 deaths (Frank et al. 2011). This was ultimately linked to the consumption of uncooked vegetable matter, in particular, uncooked fenugreek seeds (European Food Safety Authority 2011). The 2013 European horsemeat scandal includes horsemeat from a Romanian abattoir, which was shipped to the Netherlands, and then a French processing plant, which was shipped to the UK for human consumption. These multinational food transport chains were initiated at a French meat fair, and the meat was traded by a company registered in Cyprus (Traynor et al. 2013).

Food chains are becoming increasingly complex – not only are food-borne illnesses spread across large populations, but also the distribution chains and ownership of the trading partners can cover a number of different countries, each with a different set of laws. This can make it very hard and time consuming to track down the source of contamination. Often the harms can be mitigated by rapid and coordinated responses, but the more complex the practical and legal frameworks, the greater the security risks. The basic concern here is that the complexity of the systems of food production and distribution increases vulnerability of the systems to deliberate attack: the

more steps there are, the greater the potential points of attack. Further, the increased complexity could increase the impacts: rapidly identifying the causal biological agent and the malicious actor (s) are both essential to mitigating the impacts of attack, and this identification is made much harder by the complexity of the systems and the plurijurisdictional nature of the modern food industry.

Essential to harm reduction is through rapid identification of the causal agent – here meant as the specific toxin that is harming people. Wein and Liu's analysis suggested that, given the existence of a botulinum antitoxin, the harms from a botulinum outbreak in the milk supply can be mitigated through rapid identification of the toxin (Wein and Liu 2005). However, despite the importance of rapid organized responses, Schlosser describes the slow response of public health officials in the face of hamburger poisoning. Importantly, Schlosser shows that in response to the 1992 *E. coli* outbreak, Jack in the Box updated their safety practices and have since been free of any major repeats (Schlosser 2003, pp. 210–221). Control and verification would include checking of employees and the potential for malicious actors to access food production systems. Finally, consumers and indeed other government emergency and security agencies need to be rapidly and effectively informed of given risks resulting from malicious actions.

Underpinning these responses is traceability in food chains, traceability that operates rapidly across national and international regions. Food traceability is common in food production industry and is commonly required by national and international laws (Coff et al. 2008, p. 3). The benefit of working with existing food traceability processes to aid in securing against deliberate attack is that this “retrofitting” can build from established practices and could plausibly reduce industry and worker opposition to additional oversight mechanisms. This is not to say that traceability systems are a panacea to biosecurity risks in food systems – given the relatively low likelihood of terrorist attack, such systems could divert resources from the likelihood of non-malicious contamination. Secondly, any oversight mechanisms and processes would need to be appropriate

to the given sector of the food industry – preventing the addition of botulinum toxin to a milk supply is going to require very different oversight to securing a salad bar against *E. coli*.

That said, general methods that improve supply chain integrity, such as defining hazard analysis and critical control points (HACCP) (Roberts 2008, p. 183; Schlosser 2003, pp. 215–222), are likely to be useful across a range of practices. Moreover, such HACCP standards would need to include risk assessments of potential malicious activity. However, as the horsemeat scandal shows, such supply chain integrity and the capacity for rapid response to concerns are not currently assured (Traynor et al. 2013). Secondly, following Wein and Liu's analysis, basic food safety training may not be enough – food supply chains need effective security measures too, to prevent against deliberate acts of harm. A problem here is who takes official responsibility for oversight, an issue made more complex by the frequent multinational supply chains. Finally, given the low levels of actual food bioterrorism, there are issues of whether the cost of securitizing the food chains through new HACCP protocols against deliberate attacks outweighs the risks of not responding.

Summary

This entry has raised biosecurity of food systems as an important area in the ethics of food and agriculture. It compared and contrasted food security with food safety, discussed different ways of conceptualizing food biosecurity, and focused on biosecurity understood in a national security context. The entry then looked at biosecurity of food systems and showed why food systems are particularly concerning as targets of attack. It finally raised issues of food traceability and how biosecurity of food systems can figure in more traditional accounts of traceability.

Introduction

When the public in Europe turned against GM foods following first large-scale marketing of a GM crop – soy shipped from the USA – in 1996, many were taken by surprise. For once a political process had been launched while the controversial

technology was still in the pipeline. Moreover, the resulting regulation was widely believed to provide a social contract between the critical publics in Europe and those in favor of GM foods.

This contribution discusses the changing focus of political processes addressing biotechnology and GM foods. Starting with the first call for a regulation of biotechnology in the USA in the early 1960s, it tells a story about how policies in North America and Europe regarding a new and controversial technology have developed. Differences between Europe and North America regarding biotechnology policy styles and interpretations of “precaution” are addressed.

A key storyline is how policies reflect dominant framing of biotechnology as a hope, a risk, and a moral or ethical problematic technology. A mismatch between the way GM food was framed in the European biotech policies, excluding the ethical concerns of the European publics, is thus suggested as an explanation of Europeans resistance towards GM foods in 1996.

From Facilitation of Hope to Governance of Risk

Until the late 1960s the politics addressing what is today loosely referred to as “modern biotechnology” reflected an inherited framing of these technologies. During this period modern biotechnologies were important elements of a modernization project in which the new technologies were seen as a future source of material prosperity and hope for society. Thus, private sponsors and public funding organizations in North America and Europe focused on funding research in biotechnology, facilitating the many promises. The technology itself lived a relatively unnoticed life, primarily in research facilities based in universities. The governance of these research activities was outside the public eye. As has been noted, the public policies that emerged in the 1950s remained largely uncontroversial until the late 1960s: modern biotechnology, together with other new and promising technologies, was a new domain that would ideally facilitate economic development in society (Gottweis 1998).

This was true of the area of biotechnology concerned with DNA. Genetic biotech includes a range of different technologies working at the molecular level, manipulating or cloning existing hereditary material. After Watson and Crick's discovery of the structure of DNA in 1953 genetic technologies – or recombinant DNA technology, as it was referred to then – lived silently in the research laboratories. Although it was recognized that this new scientific domain provided insights into some fundamental questions about life and living organisms, genetic technologies were rarely if at all problematized in the public sphere or taken up in political discussions.

This changed when US scientists showed in the early 1970s that it was possible to join DNA from distinct species in a host cell and thus potentially manipulate the hereditary features of any living organism. The first reaction to this discovery came from some of the scientists involved. One of these was the US biochemist Paul Berg, who together with colleagues published what has become known as the “Berg letter” in *Science* in 1974 (Berg et al. 1974). In the letter they voiced their concern at the risk of creating novel types of infective elements with unknown and unpredictable properties with the technologies they themselves were involved in developing. The Berg letter called for a voluntary moratorium in rDNA research until proper safety procedures and regulation were in place. The following summer, rDNA technologies were once again debated at a conference in Asilomar, California. The outcome of this meeting was, on the one hand, a decision to lift the self-imposed moratorium and resume research in rDNA techniques and, on the other hand, a list of recommendations on safety procedures when handling rDNA in laboratories.

Although these early discussions addressed neither GM foods nor ethical issues, it is fair to say that the Berg letter and the recommendations produced at the Asilomar conference had huge impact GM food governance in the decades to come. The previous framing of genetic technologies as an instrument of modernization was extended now; it came to include a critical component questioning the risks of negative impacts on human health and the environment. This new, additional risk framing

influenced policy discourse significantly in the years to come. Thus, safety concerns were mirrored in the first efforts in GM regulation, namely, the guidelines for publicly financed research involving rDNA issued by US National Institutes of Health in 1976. Ten years later, the OECD issued guidelines on the way member states should handle biotechnology, expanding the concerns to cover consequences for the environment.

In the decades after the mid-1970s, new techniques, such as cloning and stem cell technology, were added to the portfolio of genetic technologies. The technologies moved from the research laboratories towards industrial application and marketable products. And following this the content of the risk discourse has changed – going beyond the initial concern about new health hazards due to infective elements, it has come to include concerns about the risks presented by, for example, GM plants and animals released (or escaped) into the environment and by unintended gene transfer between manipulated and wild species. Thus, risk became, and still is, an important part of the politics and regulation of the genetic technologies. This was reflected in political discussions in the 1980s which preceded the regulation of genetic technologies in the EU as well as its member states. These policy processes generally took place within a frame in which genetic technologies were seen as a useful technology with potential risks that needed to be regulated (Torgersen et al. 2002). The risk focus is evident also in two EU directives on contained use and deliberate release of genetically modified organisms adopted in 1990. In these directives the concerns addressed were limited risks to the environment and human health. Later, in 2003, the UN Cartagena Protocol on biosafety confirmed the importance of risk framing, taking the regulation of risks to the environment and human health to an international level (Secretariat of the Convention on Biological Diversity 2000).

At first glance, risks may seem to have been, if not the only, then the dominant framing of biotechnology policies in the 1980s. It is important to remember, however, that this new problematizing discourse existed alongside other policy discourses rooted in the framing of biotechnology

as promise. Although these other frames were not as manifest as the risks, a great deal of biotech policy in both Europe and North America was still about facilitating research and development. Within the European Framework Programs supporting research and development, for example, massive sums were reserved for the research and development of genetic technology and other biotechnologies. An important element in this was financial support for basic research and its applications in the food industry.

In addition to direct financial support of the research and development of biotechnologies in the agri-food sector, policies have also addressed the barriers to industrial applications and to the marketing of ingredients and food products based on research results. In part, such policies have been aimed at settling intellectual property rights and in that way securing investment in the research and development of food biotechnologies. At the core of these discussions lay questions about the interpretation, or nature, of inventions and about whether living organisms are patentable. The questions were first settled within the national and supranational patent institutions and only later in EU directives.

A key event in the patent disputes was the Chakrabarty case in the USA. In 1982 the Supreme Court ruled that patentability depends on human intervention. This decision paved the way for the patentability of genetically manipulated plants and later animals. Likewise, in 1983 the European Patent Office granted Ciba-Geigy the right to patent seeds genetically manipulated to be herbicide resistant. During the following years the patentability of genetically manipulated living organisms was the subject of intense policy discussions in the EU. These finally ended with the adoption of a Patent Directive in 1998 which stated “Inventions which concern plants or animals shall be patentable if the technical feasibility of the invention is not confined to a particular plant or animal variety” (European Parliament and Council 1998). The Chakrabarty case, the Ciba-Geigy decision, and the EU directive all mark a break with the so-called “product-of-nature” doctrine that had previously informed people’s thinking. According to the product-of-nature

doctrine, patentability cannot be granted to objects found in nature (Davis 1995).

Reframing GM Foods as an Ethical Issue in EU

In the early 1990s regulatory systems had been set up on both sides of the Atlantic in order to mitigate side effects on human health and the environment. In the USA, regulation of GM foods was based on the fundamental principle that genetic technologies are comparable with other technologies and do not themselves raise particular concerns. Following this logic, risks were handled in the USA within the existing regulatory framework, which focused on products. This so-called “product-based” regime was different from the more “process-based” regulation in Europe (Jasanoff 2005). Hence, Europe exercised a more precautionary approach – and one presupposing that genetic technology, in its nature, differs from other technologies and requires specifically tailored regulation. The process-based regulatory strategy resulted in the adoption of two EU directives specifying how member states should ensure the regulation genetically modified organisms. One directive regulated the deliberate release of GMOs into the environment (e.g., in agriculture). The other regulated enclosed use of GMOs in, for example, industrial facilities.

It is characteristic that in Europe as well as in North America, policy discourses on GM foods and agriculture largely excluded wider ethical or moral concerns until the mid-1990s. The omission of ethics in the political discourse cannot be explained by an absence of ability, or will, to discuss ethical aspects of modern technology. Other uses of technologies directly involving humans – e.g., in vitro fertilization and abortion – engage a long tradition for concern about the ethical aspects of medical technologies. Similar observations could be made about genetic engineering, where wider ethical questions had largely been reserved for applications involving humans. By contrast, applications for use in agricultural and food production were by and large kept within the risk frame.

The situation in the early 1990s in Europe was that a regulation believed to meet the concerns of the public, and at the same time facilitate the use of the new genetic technologies in agriculture and food industry, was in place before the first large-scale marketing of GM foods in Europe. To some extent, this may have been a lesson from the introduction of nuclear power, the other major and controversial technology developed and applied in the postwar years, and one that appeared a few decades before GM. In many countries nuclear power was introduced without taking public concerns about the risks into account – and the result was, in many cases, lasting social conflict. Thus, the directives can be seen as part of a between a concerned European public and the agri-food sector, hoped to ensure a peaceful application of the technologies.

In the autumn of 1996, the spell was broken. This happened when the first large-scale marketing of GM foods in the shape of GM soy took place in Europe. Despite the fact that the shipments only contained about 2% of Monsanto's Round-Up Ready Soy, genetically manipulated to resist the herbicide Round-Up, consumers in several European countries reacted with demonstrations and consumer boycotts. In spring 1997, shortly after the soya issue peaked, the birth of Dolly, a cloned Dorset ewe, was announced. Although, strictly speaking, Dolly was a medical application of biotechnology, the mere fact that scientist now had demonstrated that cloning was possible revived and fuelled controversy over GM foods, particularly in Europe.

In many ways, the second half of the 1990s marked a transition away from a European political discourse on GM foods, which, at the programmatic level, now also included some of the concerns previously excluded. It is striking that there were almost no studies of public perceptions in the 1980s. Up to, and indeed following, the reappearance of the controversy, several qualitative and quantitative studies showed that, beyond risk and usefulness, public concerns now centered on ethical issues, as well as questions about transparency in democratic decision-making (e.g., Marris et al. 2001; Lassen and Jamison 2006; Gaskell and Bauer 2002). Some studies even

found that the ethical concerns had a veto-like nature (Wagner et al. 1997; Ten Eyck et al. 2001). Others stressed the existence of a strong public voice demanding evidence of the specific societal usefulness of GM foods before they could be accepted – economic benefits to companies and individuals were not enough (Lassen et al. 2006).

Irrespective of the way public concerns over GM foods were analyzed, many of the studies supported the conclusion that the reappearance of the European controversy over GM foods was the result of a mismatch between national and EU policies and the nature of the public concern. At the political level the controversy, and the reframing of GM foods, resulted in a de facto moratorium in which a decisive majority of member states blocked approval of new GM foods in the EU in 1999 (Levidow and Carr 2010). The moratorium was lifted in 2004 following a revision of the EU regulation requiring traceability introducing a possibility of requesting nonmandatory consultation of the Commission's committees on ethics.

Although this development illustrates the reframing of policy discourse on GM foods, the fact that the results of ethical consultation are not legally binding does not seriously challenge science-based decision-making over GM foods which still focuses on risks. Meanwhile the EU Commission has proposed a revision of the existing legal framework, making it possible to combine science-based risk regulation "with freedom for Member States to decide whether or not they wish to cultivate GM crops on their territory" (European Commission 2010). Although the Commission stresses the importance of securing coexistence for GM, conventional and organic production systems, and what they call the member states' "regional and national specificities," it is far from clear to what extent the proposed revision would enable member states to include wider ethical concerns.

Transatlantic Battles over the Precautionary Principle

GM foods are not only subject to national regulation in individual countries and legislation at

EU level but also governed by the treaties regulating international trade. Once GM foods arrived at the market, during the 1990s, and exported, it was clear that the national and EU regulations were not necessarily in accordance with the principles of international trade laid down in treaties within the WTO system. These tensions were demonstrated in the dispute between the USA, Canada, and the EU over North American exports of beef from cattle treated with recombinant growth hormones to EU markets in 1998. They arose again in 2003 when the USA, Canada, and Argentina challenged the *de facto* EU moratorium imposed following the soya crisis. Both cases demonstrated a conflict between European governance of GM foods, stressing precaution, and the American, less precautionary, approach (see Anker 2012 for an elaboration of the WTO controversies and the role of the precautionary principle).

In essence, the precautionary principle stresses that in cases where the available scientific data do not allow a complete evaluation of the risks, decisions should respect the uncertainty. With reference to the precautionary principle, the EU banned the import of recombinant bovine somatotropin (rBST) meat in 1987, claiming that some uncertainty existed regarding the risks it presented to humans – a decision opposed particularly by the USA, who successfully challenged the import restrictions before the WTO in 1997. The complaining countries insisted that existing risk assessments cleared the rBST meat of risks to humans and demanded that the EU give up the ban. Similarly, the EU was challenged before the WTO on the *de facto* moratorium. Although both cases challenge the EU's right to regulate GM foods using the precautionary principle, this does not mean that the precautionary principle is not accepted outside EU. Both the Rio Declaration and the WTO system include interpretations of the principle (Anker 2012). Thus, the disputes are rather about the level of uncertainty required before a nation, or region, can claim a right to regulate trade and production and whether the alleged uncertainty is purely theoretical or has scientific backing.

Involving the Public

During the 1980s genetic technologies moved from the stage of basic research towards applications in agriculture and the food industry. The first applications, illustrating what was to come, were seen in the 1980s; they included uses of the genetic technologies in enclosed industrial facilities producing, for example, enzymes and other processing aids for the food industry. Also field trials of manipulated plants with new properties, such as crops that were resistant to pesticides, took place during the 1980s. This move from the laboratory to applications in the agri-food sector happened alongside increasing political awareness of the necessity to govern science and technology.

As noted above, discourses about science and technology were, in the years following the Second World War, generally positive. Optimism prevailed and science and new technologies were typically framed as means to wealth and societal progress. This resulted in a *laissez-faire* policy. During the 1960s and 1970s, an increasing number of reports, however, documented negative impacts of the industrial society on health, the environment, working conditions, and so on. Following this, it was gradually recognized that technological developments were in some cases accompanied by risks and undesired side effects that had the potential to cause social controversies.

Following this awareness of potential societal conflicts over technologies, technology assessment emerged as a new discipline during the 1970s. Technology assessment was seen as a tool facilitating the development of adequate policies for handling, or preventing, the negative impacts of new technologies. In assessing and predicting positive as well as negative consequences, the aim was to improve the basis of decision-making and, not least, to identify potential areas of future controversy. Since this took place while genetic technologies were migrating from the research labs towards industrial and agricultural application, these new technologies were subject to intense monitoring and assessment.

Initially, technology assessment of genetic technologies was based primarily on expert consultations. The US Office of Technology

Assessment, established in 1972, led this trend. For example, it introduced “consensus conferences,” at which groups of scientific experts were gathered and asked to reach a consensus on a given issue. During the 1970s and 1980s, most assessments of genetic technologies followed this expert trend. The interpretation of public reservations about genetic technologies, and thus the explanation of the pending controversy, was that the public were laboring under scientific illiteracy. This “knowledge-deficit” approach resulted in recommendations urging policies which, besides stimulating research and regulating the risks, aimed at informing and educating the public about the “true nature” of genetic technology. The expectation was that increased information would fill in the knowledge gap and result in acceptance of the technologies – an idea that has been challenged by survey results indicating that opposition is often greater in countries with high levels of knowledge (Biotechnology and the European Public Concerted Action group 1997) – suggesting that the relation between attitude and knowledge is more complex.

Critics of expert-based assessments and the knowledge gap, however, argued for a technology policy that also included lay assessments (Schot and Rip 1997). During the 1980s this resulted in the development of technology assessment into a more participatory discipline, and since genetic technologies were among the most hyped and controversial technologies at this time, they were assessed in terms set by this new discipline. The new, more participatory approach to technology assessment that was applied in many countries all over the world was initiated and first institutionalized in European countries with a stronger tradition of participatory democracy. Thus, institutes like the Dutch NOTA, later the Rathenau Instituut, and the Danish Board of Technology were the nexus of developments of a number of participatory tools involving the public more or less directly in decisions about genetic technologies and other technologies. In addition to existing sociological methods only facilitating indirect participation by means of focus group interviews, or surveys, these institutions developed new methods that see participation as an interaction

between decision makers and the public. Rather than changing and educating the public, this new approach aims to accommodate the genetic technologies to public concerns.

By 1996, as the soya case hit Europe, it was clear that there was a mismatch between risk-focused policies and the worries people had in many European countries. Among the many participatory initiatives launched over the following years, as means to understand and handle this situation, were genuine participatory activities, like public hearings, citizen forums, Delphi studies, and consensus conferences, inviting the public to participate in a more direct way in the policy process. One of the more noticeable activities was GM Nation, launched in the UK in 2002. The aim of GM Nation was, on the one hand, to promote a deliberative process leaving the framing of GM issues to the public and, on the other, through this, to inform the Government’s decision-making.

While it is hard to pinpoint any direct and measurable effects of the participatory activities on GM food governance, there is little doubt that there has been an indirect impact. Thus, participatory methods have given the public concerns a voice in the policy discourse on GM food and contributed to discursive changes. Earlier ethical concerns were largely confined to policy discourses covering in vitro fertilization, human cloning, gene therapy, and other human or medical applications of the genetic technologies, while policy discourses on GM foods were limited to risks and benefits. Since the mid-1990s, particularly in Europe, GM foods have been framed increasingly as an issue also including ethical aspects. Thus, although risks and economic benefits remain the dominant frame, new aspects addressing naturalness, integrity, distributional justice, and responsibility pop up from time to time alongside discussions demonstrating a tension between sheer economic and broader societal benefits.

Governance “Making GM Foods Happen”?

From their humble beginnings in the 1960s, the policy processes around GM foods have been, in

effect, a means of making biotechnology happen (Jasanoff 1995). Apart, perhaps, from the first anxious reaction of scientists in 1974, the genetic technologies have rarely if ever been seriously challenged in the policy process. Rather the aim has been to find a way to tailor the technologies to society by setting up regulations shaping their use and by making sure that public concerns are met. It can be argued that this has been carried out with some success with the construction of science-based risk assessments. However, it remains uncertain to what extent public concerns about issues other than risks can be handled. Despite attempts to manage these ethical issues, they are still largely left to market-based governance, and as long as the regulation of ethics rests with the market, the risk of controversy reemerging must surely loom large.

Summary

The governance of genetic technologies used in food production has, since its beginning, aimed to facilitate the development and application of these new and promising technologies as part of an ongoing modernization project. On the one hand, this has been realized by policies supporting research and development and paving the way for the food business. On the other hand, policies have addressed the many concerns about unwanted side effects of the technologies and established regulatory frameworks controlling these. This governance of side effects has moved from a focus on safety and human health in the early 1970s, over risks to health and the environment in the 1980s, to include broader ethical concerns in the years following 1996.

Although the overall aim of facilitating the development and application of GM food technologies has been shared by policy makers in North America and Europe, the regulatory setups are different across the Atlantic. In the USA, for example, regulation of GM foods is based on the fundamental principle that genetic technologies are similar to other technologies and should be handled within the existing regulatory framework. This product-based regime is different from the process-based approach taken in Europe, which sees genetic

technology as different from other technologies and thus as something requiring its own regulatory framework. In addition, Europe has taken a more precautionary approach to governance than the USA. And Europe, unlike the USA, has striven to include ethical aspects in regulation. So far, however, this has not resulted in binding regulations. By and large, ethical concerns have been left to be regulated by markets on either side of the Atlantic – leaving the door open to a revival of the public controversies of the 1980s and 1990s.

Biotechnology for Environmental Purposes

Sven Ove Hansson

Division of Philosophy, Royal Institute of Technology, Stockholm and Swedish University of Agricultural Sciences, Uppsala, Sweden

Introduction

Agriculture accounts significantly for the environmental destruction caused by human beings. In

the period from 1700 to 1990, the global area of cropland was increased about 5.5-fold and that of pasture land 6.6-fold. In 1990, 29 % of the world's original forest areas and 49 % of its grasslands, steppes, and savannahs were taken by agriculture (Goldewijk 2001). Agriculture is also responsible for about 80 % of the currently ongoing deforestation (UNFCCC 2007, p. 81). This massive loss in natural habitats has led to an ongoing dramatic decrease in biodiversity. Deforestation also contributes to the greenhouse effect by reducing the removal of atmospheric carbon dioxide. In addition, agricultural practices give rise to a considerable number of other environmental problems. Pesticides cause damage to wildlife. Fertilizers cause eutrophication. Tilling and overgrazing result in erosion and soil degradation. Irrigation leads to changes in water levels, water flows, and the atmospheric circulation of water. Several farming practices release gases that contribute to the greenhouse effect: carbon dioxide from tractors and machinery, methane from ruminants, and nitrous oxide from fertilizers.

There is an urgent need to reduce the environmental damage caused by agriculture and to prevent further extensions of farmland into the wilderness. This will be difficult due to the pressure from population growth and in particular from increased demand for meat. Many types of measures will be needed. This entry is devoted to possible contributions from advanced plant breeding that deploys biotechnology to provide farmers with crops and varieties that cause less detriment to the environment.

Biotechnology is a broad and somewhat vague term. Major biotechnological tools used in plant breeding include (1) traditional genetic modification (GM) in which a gene is moved from one organism to another by means other than natural reproduction, (2) gene editing in which specific genes are changed without the introduction of extraneous genetic material, and (3) marker-aided breeding in which genetic information is used to improve the selection of individual plants for use in crossbreeding.

Section “[Pest Resistance](#)” is devoted to breeding for pest resistance and reduced use of pesticides, and section “[Other Environmental Improvements](#)” to breeding for other

environmental improvements. Section “[Increasing Yields](#)” discusses breeding for increased yields and section “[Energy Production](#)” breeding of energy crops. In section “[Ethical Issues](#),” the major ethical issues are summarized.

Pest Resistance

Pesticides have contributed considerably to improved food security by reducing the risk of famine due to pathogens or pests devastating the harvest. But the use of pesticides has large negative effects on the environment and human health. Insecticides tend to harm nontarget insects, not least pollinators such as honeybees that are essential both for agriculture and for the wild flora (Krupke et al. [2012](#)). Pesticides that bioaccumulate can have disastrous effects on animals that live on plants or plant eaters, in particular birds. Humans are exposed to pesticides in two major ways: through occupational exposure that affects farmers and agricultural workers and through pesticide residues in food, affecting the general population. Occupational exposure to pesticides is a major cause of fatal poisoning in Third World countries. The International Labour Organization (ILO) estimates that about 17,000 (unintentional) fatal poisonings with pesticides take place each year, comprising 10 % of the fatalities in the agricultural sector (Rice [2000](#)). Both the environmental and the health detriments of pesticides are particularly severe in Third World countries.

A wide variety of improvements in agricultural practices, including crop rotation and mechanical and biological pest control, can significantly reduce the need for pesticides. Plant breeding can make crucial contributions by offering farmers pest-resistant cultivars.

Currently, the dominant biotechnological contribution to pest resistance is the introduction of genes from the soil bacterium *Bacillus thuringiensis* (*Bt*) into various crops including maize, soybean, and cotton. According to a meta-analysis of the literature, the use of *Bt* crops has on average reduced the use of chemical pesticides by 42 % and increased crop yields by 25 %. (Klümper and Qaim [2014](#)) (This

corresponds to a 54 % reduction in the use of pesticides per unit of harvest.) There have also been reductions in occupational exposures to pesticides and in the content of both pesticide residues and mycotoxins in the product (Qaim [2009](#); Wu [2006](#)).

Many currently ongoing breeding projects aim at providing crops with resistance genes from their wild ancestors or relatives. This has been described as “back-to-nature” breeding since it often provides plants with resistance traits that have since long been lost in breeding that selected for other traits (Palmgren et al. [2015](#)). In many cases the gene in question makes the plant itself produce a substance that is toxic to insects that attack it. Just like synthetic pesticides, these “natural pesticides” can be toxic to nontarget organisms. They must therefore be carefully evaluated for harmful effects on humans and other nontarget organisms. For instance, some wild relatives of potato have high concentrations of solanine that is a natural pesticide but unfortunately also toxic for humans. However, generally speaking, the production of a (natural) pesticide in the plant itself is a much better “mode of application” than spraying the field with a (synthetic) pesticide. The latter method leads to a dramatically larger exposure of nontarget insects and their predators. Furthermore, in many cases the plant will only produce the natural pesticide when under actual attack. From the viewpoint of environmental protection, spraying crops with synthesized pesticides can be described as a crude and rather primitive method as compared to the cultivation of crops with built-in capacity for on-demand production of substances that ward off an attack.

There is no way to achieve pest resistance once and for all. Pests evolve in response to new resistance mechanisms, for instance, by developing immunity to (natural or synthetic) pesticides. Wild plants respond to this by again developing new resistance mechanisms, but agricultural plants cannot do so since they have been removed from the natural evolutionary processes. Hence, plant breeders have to provide them continuously with new forms of resistance in order to keep down the pests. Modern biotechnology has provided plant breeders with tools that are highly efficient for resistance breeding. If a modern

crop is crossed with a wild relative that has a desirable resistance trait, then the offspring will also inherit various agriculturally undesirable traits. These can be removed gradually by repeated “backcrossing” with the original crop, but this is a time-consuming process that takes many generations of the crop. Resistance traits are often located in a single gene and can therefore be obtained in a single step of gene transfer or gene editing, without the need for backcrossing.

Other Environmental Improvements

In addition to reduced use of pesticides, plant breeding can contribute in several other ways to a more environmentally sustainable agriculture. Important such breeding goals are reductions in tilling, fertilization, irrigation, and greenhouse gas emissions.

Reduced tilling. In spite of being an age-old agricultural practice that is taken to be a “natural” part of farming, tillage has severe environmental disadvantages (Yao et al. 2010). It leads to soil erosion and to runoffs of surface waters that contain pesticides and nutrients. The transportation of pesticides can harm species in surrounding aquatic and terrestrial habitats. The transportation of nutrients increases the need for fertilizers in the fields from where they are lost and at the same time causes eutrophication of the lakes and coastal waters to where they are transported. Furthermore, modern tillage makes use of fossil fuels, thereby contributing to greenhouse gas emissions. Therefore, cultivars that need less tilling than those currently grown would be an important contribution to a more environmentally friendly agriculture.

Since tilling is largely performed to control weeds, it can be reduced if weeds are controlled by other means. Currently this is achieved with the use of herbicides, often facilitated by the use of herbicide-resistant crops. However, this is a two-edged sword since herbicides can have considerable negative effects on the environment, not least on birds that feed on insects living on affected wild plants (Newton 2004). Therefore plant breeders are investigating other means to reduce

tilling. A particularly interesting option is to breed for perenniality. Many annual cereals have perennial wild relatives with a genetic material that can be used for this purpose (Downes 2000). However, perennial farming systems run the risk of becoming more susceptible to pathogens and pests since they do not make use of crop rotation for controlling them. Therefore, resistance breeding is particularly important for perennial crops.

Reduced use of fertilizers. Plants need nutrients such as nitrogen, phosphorous, and potassium to grow. Fertilizers containing these and other nutrients are used to increase plant growth and obtain a satisfactory yield. However, runoff in particular of nitrogen from fertilized fields is the major cause of eutrophication. Therefore, plant breeders are investigating several ways to decrease the dependence on fertilizers. Several traits from wild plants are under investigation that would improve crops in terms of their uptake of nitrogen from soil or their metabolic use of it. Another interesting option is to reduce nitrification, i.e., the process in which soil bacteria make nitrogen inaccessible to the crop by forming nitrite and nitrate (Subbarao et al. 2007). A more radical proposal is to transfer a property from legumes (plants of the bean family) to cereals and other nonlegume crops. Legumes absorb (fixate) nitrogen from the atmosphere through a complex symbiosis with rhizobia, a class of soil bacteria. If this trait could be transferred to cereals and other nonlegume crops, then the use of nitrogen fertilizers could be substantially reduced. However, the research aiming at establishing nitrogen fixation in nonlegumes is still at a relatively early stage (Cocking 2009).

Reduced need for irrigation. Drought is a major cause of harvest losses, in particular in the tropics. The traditional measure to secure harvests against drought is irrigation. Climate change leads to desertification (increase in arid land), further increasing the need for irrigation and the pressure on limited water resources. Due to the considerable environmental disadvantages of irrigation, ways to make major crops more drought tolerant are currently being investigated, and several promising approaches have been identified (Mir et al. 2012). For instance, significant progress has

been achieved with genomic prediction for selection in maize to obtain drought-tolerant germplasm suitable for cultivation in Sub-Saharan Africa (Beyene et al. 2015).

Reduced greenhouse gas emissions. Agriculture is responsible for about a fourth of the global greenhouse gas burden (Bennetzen et al. 2015). Several of the measures already mentioned would decrease greenhouse gas emissions. When tilling and irrigation are reduced, emissions of carbon dioxide from fossil-fueled tractors and pumps will also go down. A reduction in the use of nitrogen fertilizers will diminish the releases of nitrous oxide, another greenhouse gas. A further interesting example is methane emissions from the cultivation of rice. Soil bacteria in rice fields produce large amounts of methane, and rice fields are the largest anthropogenic contributor to atmospheric methane. The addition to the rice genome of a single gene from barley has been shown to reduce the prevalence of methanogenic bacteria and thereby significantly reduce methane emissions (Su et al. 2015).

Increasing Yields

The global environmental impact of agriculture depends to a large extent on the total area used for farmland. Natural habitats are already so curtailed that a further large-scale expansion of farmland is bound to have devastating effects. Therefore, environmental improvements on the already cultivated lands will be counterproductive if they lead to decreases in yield that have to be compensated by additional farmland in order to ensure sufficient food supplies.

The situation is further aggravated by the pressure from population growth and an expected increase in the demand for meat. A shift from a vegetarian diet to the diets rich in meat that are common in industrialized societies leads to at least a threefold increase in the required farmland per person (Gerbens-Leenes and Nonhebel 2002).

There are large variations in yields, depending not least on differences in agricultural practices. For instance, in 2013 a Zimbabwean farmer used on average 11 times more land than a colleague in

the USA to produce the same amount of maize, in spite of having equally good climatic conditions for this crop (Long et al. 2015). Other things being equal, it is of considerable advantage for the environment to keep down the need for additional farmland. This can be achieved by dietary choice (less meat), efficient production methods (high yields), and decreased wastage at all stages of the value chain.

Unfortunately, many yield-increasing technologies have substantial harmful effects on the environment. This is exemplified by irrigation beyond the capacity of local water supplies, fertilization that increases nutrient leakage, and not least the use of pesticides that are toxic to nontarget organisms (Pimentel 2005; Mitra et al. 2011). However, there is no direct or unavoidable connection between yield increases and environmental damage. Some measures that increase yields can have comparatively small negative effects on the environment. This includes mechanical pest control and the use of cultivars with increased nitrogen use efficiency, a high harvest index (grain mass as percentage of the plant's mass), and increased tolerance to climatic and other environmental stresses such as drought, flooding, high salinity, and high and low temperatures. These are all traits that can be targeted in modern plant breeding.

An interesting method to increase yields is to improve photosynthetic efficiency (Long et al. 2015; von Caemmerer et al. 2012). Most plants have the C_3 type of photosynthesis but, for example, maize, sorghum, and sugarcane have the C_4 type. C_4 plants have a competitive advantage over C_3 plants under conditions of drought, high temperatures, and shortage of nitrogen or carbon dioxide. C_4 plants tend to have higher yields and use water and nitrogen more efficiently than C_3 plants.

Energy Production

Ethanol for fuel is produced from maize, sugarcane, and other sources of cellulosic biomass. Oil crops such as sunflower, rapeseed, and soybean are also used for fuel production. However, biofuel production competes with food production

for farmland, and increases in the total farmland area are highly problematic. In practice, the demand for transport fuels is so large that the contribution from energy crops cannot replace fossil fuels. Researchers have therefore turned to oils from microalgae as a potential source of energy. Microalgae produce oils using sunlight more efficiently than conventional crops. They grow much faster than traditional oil crops; the biomass can double within 24 h. Theoretically, they can produce between 10 and 100 times more oil per square meter than oil crops, but much remains to make this option economically viable (Greenwell et al. 2010). Another option is to use algae or cyanobacteria (“blue-green algae”) that produce ethanol, methane, or hydrogen. This requires various biotechnological adjustments of the organisms in question. For instance, naturally occurring species that produce hydrogen reabsorb most of the hydrogen they produce. By turning off this reabsorption, their hydrogen-producing capacity can be much increased (Xia et al. 2016).

Ethical Issues

The use of agricultural biotechnology for environmental improvement is related to several ethical issues:

1. *The evaluation of biotechnology as a generic technology.* Agricultural biotechnology is a generic technology, i.e., one that can be used for a wide variety of purposes. Other examples are electricity, plastic, computers, and the Internet. Generic technologies can be used for both positive and negative purposes. Their introduction often goes through an initial phase when the technology as such is criticized, and its introduction is called into question with arguments referring to its potential negative uses (Bauer 1995). In many cases this has been followed by a new phase in which the technology’s existence is accepted, and the discussion is instead focused on how its negative uses can be curbed. For a long time, biotechnology has been discussed in the former way, but there are signs of a change. The concrete proposals for environmentally beneficial uses that are now on the table create problems for the standpoint that all biotechnological products for agriculture should be rejected on principle, without an assessment of the pros and cons of the individual product.
2. *The choice of breeding goals.* In the last few decades, many governments have withdrawn from plant breeding, leaving the field to private breeding companies whose goals are of course based on commercial considerations, i.e., profits. Currently plant breeding is characterized by a strong concentration on yield, and very few full-scale breeding projects focus primarily on breeding goals such as environmental improvements, more healthy food products, or catering to the needs of subsistence farmers in the Third World. The choice of breeding goals is obviously an ethical issue, and governments have a choice whether to leave it to the market or take initiatives to ensure that plant breeding technologies are used to help solve urgent environmental and social problems.
3. *The conflict between local and global perspectives on environmental impacts.* For the individual farmer, the most obvious perspective on environmental impacts is to take the acreage for given, and ask her- or himself: “Given the farmland that I have, how can I minimize the environmental detriment?” In a global perspective, the appropriate question is instead: “Given that we have to produce sufficient food for the world’s population, how can we minimize the environmental detriment?” In the latter, global perspective, an essential consideration will be how to avoid or limit increases in the total cultivated acreage. At least two policy issues will then emerge that are typically not seen as environmental issues in the individual farmer’s perspective: promotion of land-efficient diets and measures that increase the yield per acreage. Plant breeding has an important role in developing means to increase agricultural yields in an environmentally sustainable way.
4. *Criteria for positive environmental labeling.* Many consumers wish to support environmentally sustainable farming. It is in practice

impossible for the individual consumer to evaluate the environmental impacts of each and every product that she considers buying. Positive environmental labeling aims at making pro-environmental consumer choices possible. The most influential such labeling systems classify certain products as “organic.” The criteria for positive environmental labeling are obviously an ethical issue. Consumers expect the products thus labeled to be those in their category that have the least negative environmental impact. The construction of such criteria involves quite intricate ethics-related issues such as the choice between a local and a global perspective on environmental detriments. Currently, criteria for organic food exclude genetically modified plants. However, proposals have been made to allow genetic modifications that are beneficial for the environment. One such proposal is to introduce a special category of “orgenic plants” for the production of orgenic food. To avoid undesired gene spread, such a plant should either be sterile or have received genes only from plants that it could exchange genes with naturally. Furthermore, orgenic plants should not contain genes for herbicide resistance or other properties that may be detrimental to the environment (Ryffel 2012).

Consumption; Embodiment; Identity; Representations

Introduction

While human bodies must consume food to live, lives are organized around the actual harvesting, gathering, preparing, and eating of food. These practices, particularly consumption, are deeply cultured and gendered. The ranges of appropriate body sizes and shapes are also highly gendered. In the USA, men on average are 5.5 in. taller and 29.3 lb. heavier than women (CDC 2012b). Though not all men are larger nor all women smaller, they are expected to be based on feminine and masculine body ideals. Most people strive for socially and culturally normative body sizes.

The presentation of self as a gendered person is achieved through the use of markers and symbols, including clothing, hairstyles, and jewelry. Humans manage their interactions with others using behavior and physical activities considered appropriate for one's sex category (Goffman 1959). Internal and external body image, its size, shape, contours, and ornamentation, is inextricably tied with the essential biological need to consume food as well as the validation of body presentation. Globally in heterogeneous cultures, bodies are dichotomously depicted and presented as male, whereby a body will be muscular, hairy, large, tall, and solid, or as female, whereby a body will be slender, smooth, hairless, petite, and slight. Those falling outside of the gendered descriptions of body size and appearance are often in the challenging position of sculpting, controlling, starving, or enhancing their bodies for the preferred male or female presentation of self. This entry covers the definition and ethics of body image, gendered relationships with food, disordered eating across the globe, Pro-Ana Movements, and Fatness Studies.

Body Image

Body image is defined as a person's self-perception of his or her own body. Internal body image refers to the way someone feels about his or her own body; this is psychological. External body image is how others perceive and react to bodies; this is sociological. There is an ongoing interaction between the psychological and

sociological perspectives of body image, which are inextricably linked: a person's internal body image can be vastly different from their external body image. The disconnect between what is perceived about the body and how the body publicly appears has largely been accredited to sociological factors, particularly different media representations of the ideal body (Grogan 2008).

People absorb revered and stigmatized images of different bodies through friends and family or via media including television, magazines, and the Internet. Constantly bombarded with these images of bodies, individuals are influenced to judge and consider their own perceived flaws and develop body projects (Brumberg 1997) to manage these "problems." Men and women work to achieve an idealized body image and reap the rewards of prestige, attention, or accolades in the form of positive social sanctions. One of the primary ways individuals discipline human bodies to better reflect the "ideal" body type is through the selection of food and eating habits.

The consumption of food and management of weight and body size are how body image is regulated. Furthermore, part of maintaining an acceptable body image goes beyond one's physiological shape and involves bodies acting in a culturally and socially regulated way through table manners, portion control, and expression of tastes. Seemingly trivial movements such as the way one walks or holds a fork are not merely how the body functions but also cultural imprints which adapt to norms of gendered, racialized, and classed bodies (Bordo 1993).

Gendered Relationships with Food

Food is one of the ways to express identity and group membership – as cultured or raced, as gendered, and as part of a social class. Although consumption is universally human, the ways people eat and what they chose to eat are not universal; eating practices and preferences are culturally produced (Lupton 1996; Kluger et al. 2004). Food advertisements take advantage of the need for food in ways that appeal to specific groups of people. Men and women have been socialized to eat differently. Originating with prehistoric ideas

of men as hunters and women as gatherers (Sobal 2005), eating habits and ideas transcend generations by the actions and diets of older men and women which are passed down to their children and then to their children's children. Individuals often mimic the performances that receive favorable reaction and engender generations of similar performances (Goffman 1959).

Gender can dictate the type of food that a person eats. Men are shown overwhelmingly to eat more meat and protein-based diets, in part because many societies prioritize their nutrition over that of women (Adams 2000; Lockie and Lyn 1999; Rogers 2008; Nath 2011). Men also are shown and expected to eat more meat because of what animal flesh symbolically represents. Eating meat has come to represent human's superiority over other animals because of its representation as a masculine food (Adams 2000). Eating animal flesh is used as a display of power over other animals, supposedly proving human's strength (Fiddes 1991). Though these ideas are perpetuated daily, researchers have found flaws in their fundamental accuracy. Meat as a representation of masculinity, power, and strength contradicts with what meat actually does to the human body. Despite new scientific studies that connect the consumption of red meat to coronary heart disease, eating meat, is still dominantly considered a means to strength, health, and virility (Nath 2011; Lockie and Lyn 1999). The consumption of meat has moral implications beyond its masculine representation. Philosophers debate the ethical concerns of eating meat and other foods (Kaplan 2012).

It is no coincidence that the foods marketed to women are often described as healthier and are associated with weight loss. The grand narrative of advertising food to women in high-income countries is thinness. One of the most common foods targeted at women is yogurt. Yogurt is largely considered a healthy food option. Yogurt commercials often feature dessert flavors: Boston crème pie and strawberry cheesecake. Dieting women routinely deny themselves such foods as pie and cheesecake in order to maintain the elusive "perfect body." This denial of food is culturally specific, often resonating in upper- and middle-class women whose food supply has

never been jeopardized (Lupton 1996; Counihan 1998; Allen and Sachs 2007).

Feminist scholars suggest using social, historical, and physical environment factors to explore gendered food and body image issues. Women and girls' relationship to food and their bodies have many influences beyond being ultrathin, including participation in sports, stress, and access to food (Yancey et al. 2006).

Disordered Eating

Eating disorders, disordered eating, and eating disturbances are terms used to identify clinical manifestations of skewed body images and psychologically categorized pathological eating practices. In the USA, the Diagnostic and Statistical Manual of Mental Disorders (DSM-V) describes four main categories of eating disorders. These disorders include anorexia nervosa, self-starvation; bulimia nervosa, bingeing and compensatory behaviors such as self-induced vomiting; binge eating disorder, recurrent episodes of eating significantly more food in a short period of time than most people would eat under similar circumstances; and eating disorders not otherwise specified (EDNOS), any combination of signs and symptoms typical of anorexia and bulimia (American Psychiatric Association 2013).

It is estimated that up to 24 million people in the USA suffer from an eating disorder, including anorexia nervosa, bulimia nervosa, and binge eating disorder (ANAD 2013). Up to 70 million people suffer from eating disorders around the world (Renfrew 2003). Surprisingly, in industrialized countries, eating disorders have the highest mortality rate of any psychiatric illness, yet they garner the lowest funding towards prevention, education, and research (NEDA 2013). Many insurance companies do not cover treatment. Insurance that does cover treatment often has strict regulations for qualification that are not met until the eating disorder is highly developed. This time lag is especially problematic because studies overwhelmingly show eating disorders are harder to treat the longer they are present (Dias 2003; Peebles et al. 2012).

Most people who are clinically diagnosed with the illness never fully recover (Boero and Pascoe 2012). Studies of eating disorders largely focus on women, and erroneously there are long-held beliefs that men do not have eating disorders. Men comprise 10–15% the total number of anorexia and bulimia cases in the USA (ANAD 2013). Studies have shown that men and women suffer from binge eating in similar numbers. Men seem to be more dissatisfied with their bodies when their body weight and height fall below average (Strother et al. 2012). Their body image dissatisfactions and how they suffer from these disorders reflect larger societal pressures (Weltzin et al. 2005).

Men are more likely to become obsessed with exercise because muscular toned bodies are the hegemonic masculine ideal. Muscle dysmorphia is characterized by preoccupation or obsession with muscularity and most prevalent in men, resulting in the use of anabolic steroids and growth hormones. One study suggests that the percentage of men using these substances is similar to the percentage of women with anorexia and bulimia (Strother et al. 2012).

Women in other countries, both developed and undeveloped nations, are influenced by the US standards of ideal body size. Globalization has been blamed for body image dissatisfaction and eating disorders in countries outside of the USA. Women in Fiji idealized the ultrathin body for what it represents – material wealth and a consumer lifestyle – but they did not find the thin body attractive in itself (Edmonds 2012). A study in highly Westernized Belize found that despite the high prevalence of US media, the country had no clinically significant eating disorders. A local tradition of caring for one's own body may protect young girls from eating disorders (Edmonds 2012).

Even though there are countries that defy the assumption that Westernization causes body image problems and eating disorders, there are many studies that show an increase in eating disorders outside of the USA. A study in Navarra, Spain, found that in an 18-month period, 4.8% of a 2509 sample of women ages 13–22 developed an eating disorder (Lahortiga-Ramos et al. 2005).

Most research of eating disorders and body image is conducted within the USA, a country thought of as the root of global body dissatisfaction. Significantly, Argentinians and Brazilians have increasing rates of body dissatisfaction. It is estimated that 10% of Argentine adolescent girls suffer from some sort of eating disorder. Brazil has the highest per capita use of diet medication in the world (Forbes et al. 2012).

There are many difficulties in studying the epidemiology of eating disorders because individuals suffering from eating disorders often hide their struggle and attempt to conceal their illness from doctors, families, and friends. This secrecy and shame makes community studies of eating disorders challenging and often inaccurate. Therefore, researchers base their analyses on medical records to ascertain the incidence and prevalence rates. While this technique may provide some information, it is likely that statistics about eating disorders are underestimated (NEDA 2013; Smink et al. 2012).

Studies of cultural, ethnic, and racial determinants of eating disorders and body image, mostly conducted on US-based populations, largely focus on comparative analysis of white and black women. One notable difference in body image revolves around perception. White women are found to be dissatisfied with their bodies when their weight falls into average or below average categories. Black women do not have eating disturbances until they are in overweight categories, if at all. White women suffer from anorexia and bulimia more commonly, and black women suffer from binge eating and obesity.

Many researchers believe that part of the reason black women are often heavier than white women is because they are fighting multiple oppressions and are comforted by food (Lovejoy 2001; Feinson 2011). Overall, researchers find that black communities are more accepting of different body types as attractive, resulting in fewer black women being driven to extremes to achieve unattainable thinness (Kelch-Oliver and Ancis 2011). There also seems to be less pressure from family, friends, and romantic partners to conform to Western standards of beauty (Jefferson and Stake 2009).

A study of adolescent Ecuadorian girls explores the pressure felt to both be “Western beautiful” and beautiful within their own culture. In interviews, the girls gave descriptions of beauty coinciding with Western ideas. Only women with very light or white skin and Caucasian features are recognized as the ideal beauty. The participants judged real women less harshly than models and celebrities, using the Ecuadorian word “arreglada,” meaning “well groomed,” to describe beauty. As long as the woman puts effort into her appearance and has a good heart, she is generally thought of as beautiful (de Casanova 2004). The Western hegemonic depictions of unrealistic ultrathin models have the potential to affect women and girls globally, resulting in body image dissatisfaction and confusion.

Pro-Ana Movements

Open dialogue websites made and used by women suffering with eating disorders have become a subject of interest over the past decade. The websites often include advice, images, discussion boards, videos, and audio that explain and encourage a lifestyle that integrates eating disorders. Part of engaging in these websites involves developing an online persona. These websites, referred to as “Pro-Anorexia” or “Pro-Ana,” have been deemed problematic because of their positive reinforcement of eating disorders. Many images of models and celebrities are presented as “thinspiration.” These images are often criticized as harmful and triggering, yet Pro-Ana websites are only one of many places that pictures of extremely thin models are displayed (billboards, magazines, etc.). Importantly, many women who are often very secretive about their eating disorders in public are very open about it online, resulting in two different identity performances.

These websites, accessed by anyone with the Internet, provide a space for them to discuss their issues with others who have similar problems, free from judgment (Borzekowski et al. 2010). Many of the websites have disclaimers before entering, stating that they are only meant for people who have eating disorders. Weigh-ins, posting

photographs, and food journals are all used to discourage less involved users. The users of these websites struggle with bringing their real-life bodies into a disembodied space. The community is built by those who successfully display themselves as “real” anorexic bodies (Boero and Pascoe 2012).

Women with eating disorders are often thought of as “irrational” and “in denial” of their behavior. The narratives on Pro-Ana websites contradict these statements. Many women claim to be self-aware and are making attempts to address their disordered relationship with food. Women realize the “perfect body” is virtually unachievable, yet still aspire to it. Treatment for eating disorders is highly flawed in the USA.

Fatness Studies

The proliferation of an idealized thin body type is completely incongruent with real-life global bodies. According to the World Health Organization, over 50% of the women in the regions of North America, Europe, and Eastern Mediterranean are overweight. The majority of the world lives where more people die from issues associated with obesity rather than malnourishment (WHO 2013). Fat bodies receive a comparable amount of attention as thin bodies, but in very different ways. Fat bodies are harshly criticized in the media, by the medical industrial complex, and within the general population. While fat bodies are regularly seen in public, they are rarely seen in the entertainment media, and when represented they appear as the abject body. These bodies are medicalized as unhealthy and layered with stigmatized terms such as lazy, careless, and stupid.

Fat bodies have not always been depicted as unhealthy and undesired. They once symbolized wealth and prosperity, signifying access to an abundance of food rather than having to struggle for it. Somewhere between the 1880s and 1920s, messages about fatness changed from healthy and beautiful to unhealthy and unattractive (Rothbum and Solovay 2009). Since then, fat bodies have seen a steady increase of negative attention (Gilman 2008). Fat bodies are considered a risk to

themselves as well as a drain on limited public resources, as fatness is associated with illness and disease such as diabetes and heart conditions. Individuals who are fat have reported being denied healthcare or forced to pay a higher medical premium. They are also subject to discrimination in the workplace, often not hired for physical jobs and/or jobs that interact with the public (Berg 2008).

Personal responsibility overshadows class, ethnic, and social explorations of body size. Many of the determinants that foster weight gain are rooted in industries and everyday life practices that are difficult to challenge. Many people work at jobs that require them to sit at a desk for the majority of the day without any physical activity. Food industries supply readily available, very cheap, and very unhealthy food (Lupton 2013).

Though being extremely overweight, or in medical terms “morbidly obese,” can cause some health problems, the obsession with fat bodies as a sign of unhealthiness is often unbalanced. Researchers opposing the medicalization of fat bodies explain that there is no statistical evidence that equates fatness with ill health or disease and there is no evidence that losing body fat improves a person’s health status (Lupton 2013). Fat bodies are constantly bombarded with images of ultrathin women and how they got to be that way. Diet and fitness magazines never display fat bodies but are always talking about them (Kent 2001).

In popular culture, fat bodies are consistently kept invisible. They are only shown if they are trying to become thin: “before” pictures in dieting ads and in the newly popular weight loss television series. Fat bodies are never shown as “normal” media characters or as successful, sexy, or in charge (Kent 2001). Yet, over one-third of the US population is considered obese and 69.2% of Americans are considered overweight (CDC 2012a). The lack of positive images of fat bodies serves a purpose. Fat bodies are left to feel isolated and unworthy. When they are displayed, it is only to show that there is a way to change: to choose this diet, to buy this supplement.

The stigmatization of fat bodies is justified by the idea that thinness is preferred, healthy, universally achievable, and natural. Even if eating healthy and exercising regularly were an infallible

way of achieving a thin body, there would still be challenges. Healthy food costs more money and time than unhealthy food. Food insecurity is described as the inability to acquire nutritionally adequate and safe foods (Smith and Bloomberg 2008). It has been acknowledged that lower socioeconomic areas lack access to healthy, affordable foods (White 2007). These areas often have limited access to large supermarkets, causing people to rely on smaller shops, convenience stores, and fast-food restaurants. The food obtained at these places may relieve hunger, but often lack nutritional value (Smith and Bloomberg 2008).

To counter the oppression of fat bodies, a movement of size acceptance has emerged out of feminist and queer liberation movements. Feminists have been advocating for fat bodies for decades, discussing why fat bodies should not be disparaged (Kent 2001). Acknowledging that fat bodies are not necessarily unhealthy would also help in the acceptance of larger and different bodies. A grassroots movement of healthcare workers, researchers, consumers, and activists has been trying to shift the idea of what a healthy body looks like. Health at Every Size (HAES) emphasizes healthy everyday practices and body acceptance. The actual weight and size of a body is not as important as its overall health (Burgard 2009; Lupton 2013). Many groups and individuals protest the discrimination of fat bodies. They believe size diversity among humans is natural and should be celebrated (Berg 2008).

Summary

Body image is continuously changing throughout the world. A person's external appearance converges with his or her eating practices to help form an identity. Eating and producing food is not as simple as acquiring nutrients; its symbolism is powerful and morphs and adapts through time.

Introduction

Brazil is one of the world's largest agricultural producers and exporters. Vast areas of arable land, rich natural resources, sophisticated research and technology, and highly developed domestic and international markets nurture a highly modernized agriculture industry. This agricultural juggernaut exists alongside (and competes with) a vibrant peasantry that persists in the Brazilian countryside and produces much of the food that is consumed domestically. Brazil's primary commercial crops include soybeans, sugarcane, beef, poultry, cotton, orange juice, and coffee. Important domestic food crops include manioc, wheat, corn, rice, and a vast array of fruits and vegetables. Agricultural production has risen dramatically in the last two decades, particularly in the soy and sugar sectors, as global demand for animal products and biofuels has skyrocketed. These changes in the agricultural economy in Brazil have raised a number of ethical issues. One of the most contentious within Brazil is access to and distribution of land between big agriculture and the peasantry. Violent conflicts over land often grab headlines in the Brazilian media. The illegal use of slave labor on large farms has also become a very public issue, and while the federal government has stepped up enforcement in recent years, tens of thousands of workers are still estimated to be working under slave-like conditions. Finally, Brazil is home to over 60% of the Amazon

rainforest, and the country's agricultural frontier presents a constant threat to the integrity of that ecosystem. Because the Amazon is considered the "lungs of the world," and because so many countries depend on Brazilian exports for domestic food security, many of these ethical questions are considered global issues by the international community. This essay will discuss these issues in the context of some of Brazil's most economically important agricultural commodities: coffee, sugar, soy, cattle, and horticulture. Each case provides a unique perspective on the ethical controversies described above and reveals the complexity of Brazil's agricultural landscape in a different way.

Overview of Brazilian Agriculture

There are three main commercial agricultural regions in Brazil, each with its own production profile and political-economic structure. The southern region is dominated by medium-sized commercial farms that produce crops primarily for the domestic market. The northeast produces mostly horticultural products (fresh fruits and vegetables or FFV), sugar, and coffee. The center-west is home to massive sugarcane and soybean farms (which increasingly intercrop with corn) that almost exclusively serve the export market. Alongside large-scale commercial or *latifundio* agriculture, small family farms (*minifundio*) remain an important part of the Brazilian economy. According to the Ministry of Agrarian Development, "family farming produces 70% of food consumed in Brazil, occupies 25% of the country's cultivated area, generates 75% of jobs in rural areas and accounts for 84% of establishments in rural Brazil" (Ministerio do Desenvolvimento Agrário 2012).

The tension between large-scale, export-oriented farming and smaller-scale, domestic-oriented (or even subsistence) farming is one of the main animating dynamics of the Brazilian agricultural system. These two agricultural paradigms have coexisted since colonial times but are often locked in conflict over access to land and government resources, as well as social

legitimacy and justice. Brazil's two different ministries of agriculture (the Ministry of Agriculture, Livestock, and Food Supply and the Ministry of Agrarian Development) exemplify the political division between the two modes of production. Though separated in the Brazilian political structure, these systems profoundly impact one another, and their relative contributions to functions and priorities in Brazilian society are a matter of fierce debate.

Brazilian agriculture also finds itself at the center of global environmental and human rights debates. Brazil is one of the last places on earth with significant amounts of undeveloped land that could be converted to agriculture. However, those same areas also boast some of the most biologically diverse and sensitive ecosystems on the planet. As "food crises," or dramatic spikes in food prices that occur due to commodity speculation and supply disruption, have become increasingly frequent and severe over the last decade, Brazil has become a focal point for the debate over the future of the global food system. In 2009, the UN predicted that global food production would have to double by 2050 in order to keep up with the rising global population and, perhaps more importantly, rising incomes and the increased consumption of animal protein that often results (United Nations 2009). As people around the world eat more meat, Brazil responds by producing greater quantities of soybeans and corn to feed livestock. Expanding demand for biofuels puts similar pressure on sugar markets, and the continuing profitability of cotton and beef intensifies the competition for land among these primary industrial commodities. These large monoculture *fazendas* run on hired labor, and although the vast majority of *fazendeiros* treat their workers fairly, every year the Brazilian government continues to find thousands of rural workers being held against their will in slave-like conditions (Associated Press 2012). All of these controversial questions, which will be discussed in more detail below, shape the dynamics and trajectory of Brazilian agriculture and render the sector one of the most important sites of social inquiry today.

A Brief History of Brazilian Agriculture: Colonialism to Industrialization

While comparatively little is known about pre-colonial agriculture in Brazil, there is evidence that indigenous peoples cultivated manioc and maize, as well as a wide variety of fruit, nut, and vegetable crops in the Atlantic and Amazon forests (Filho and Gamboa 1993). The earliest colonists were primarily interested in extracting and exporting brazilwood for the red dye that it produced. However, as colonies were established, so was an economy based on tropical agriculture. The first colonial cycle was dominated by sugarcane, which lasted from 1530 until 1700. The coffee cycle that followed lasted from the 1830s to the 1930s (Eakin 1997). Even after industrialization of agriculture began to take hold and the sector diversified beyond coffee and sugar, the Brazilian economy remained heavily dependent on tropical agriculture, which was responsible for an average of 55% of exports until the 1960s (Pereira et al. 2012).

In 1964, a military coup overthrew the democratically elected government, and the regime that ruled Brazil for the next 20 years pushed industrialization and urbanization that would change the face of Brazilian agriculture. The impact on agriculture of the push for industrialization was twofold. First, capital investments in agricultural production were encouraged through government subsidy programs that gave farmers cheap credit to purchase machinery. Second, the pull of developing cities contributed to a rural-to-urban migration that mirrored the process of rural depopulation that was simultaneously occurring all over the developing world. In Brazil, the rural population decreased from 64% of the country's total in 1950 to 32% in 1980 and 16% in 2010 (Pereira et al. 2012).

With a declining rural population, a national political emphasis on industrialization and modernization, and the worldwide spread of agricultural technology and research prompted by the Green Revolution, agriculture in Brazil underwent a major transformation in the mid-twentieth century. One of the most important changes was the conversion of the *cerrado* – a

mixed savannah and forest ecosystem that dominates the central plains – to agriculture. Prior to the 1970s, it was widely believed that the *cerrado* was unfit for agriculture due to the acidity of the soil. However, the country's agricultural research agency Embrapa discovered soil amendments – namely, phosphorus and lime – that would release the nutrients in the acidic *cerrado* soils and render the region the largest unexploited agricultural frontier in the world (Warnken 1999).

Despite Brazil's tremendous agricultural productivity, the country remained a net recipient of food aid well into the 1980s. Today, however, Brazil is one of the largest exporters of agricultural goods in the world and is largely self-sufficient in food. Agriculture is responsible for 35% of the country's exports and 6% of its GDP (Economic Research Service 2012). The following section discusses in detail some of Brazil's major crops and some of the ethical questions associated with particular sectors and with large-scale agriculture in general.

Major Crops

Coffee

Coffee is the commercial crop with the longest and perhaps most complicated history in Brazil. It has been a powerful engine of economic growth but is also directly implicated in the environmental, human rights, and land access controversies described above. During and immediately following Portuguese colonization, coffee plantations dominated the vast Paraíba Valley of São Paulo state, setting the stage for the industrial development that later made São Paulo Brazil's economic center of gravity. Though coffee's economic importance has diminished relative to other agricultural products in recent decades, it remains an important source of foreign exchange revenue, and Brazil remains the largest coffee producer in the world, responsible for over one third of total exports.

The coffee plantations that drove economic growth in Brazil throughout the nineteenth century were the beginning of Brazil's *latifundio* system wherein vast coffee plantations were

operated by a small number of very wealthy landowners. These plantations subsisted on imported slave labor, and conditions were notoriously brutal. Brazil was the last country in the western hemisphere to officially outlaw slavery (in 1888), but illegal slavery continues today on many of the country's large monoculture farms.

Brazil's early coffee plantations also dramatically changed the ecosystem of the Atlantic region. While much of today's attention is focused on deforestation in the Amazon, in the nineteenth century, coffee plantations devoured Brazil's extensive – and biologically rich – Atlantic rainforest. Very little of this unique ecosystem exists today, as the method by which coffee plantations were established caused profound erosion of delicate soils and rendered the land forever dependent on the application of fertilizers.

As the ecological impacts of coffee cultivation have become better understood, environmental groups are encouraging “shade-grown” coffee, a system where coffee bushes are planted underneath a diverse forest canopy. This system allows the forest canopy to remain largely intact, providing habitat for migratory birds and other wildlife. However, shaded systems have significantly lower yield than sun systems, which means that shade-grown coffee tends to be a specialty product marketed to “conscientious consumers” willing (and able) to pay more. Similarly, as labor abuses on large Brazilian coffee plantations have gained publicity (in 2007 the UN estimates between 25,000 and 40,000 workers may be working under slave-like conditions in Brazil), some consumers are demanding “relationship coffee” or coffee that is bought directly from small farmers rather than through brokers that market the coffee grown on large plantations.

Coffee was the first agricultural product to be marketed under the “fair trade” designation, which grew after the collapse of the International Coffee Agreement that controlled the global coffee trade from 1962 to 1989. While the “fair trade” market has grown significantly over the last decade, controversies are widespread over the certification process and the benefit to farmers. Some argue that the significant markup that retailers can charge for fair trade coffee in western

markets is not passed along to farmers, and others claim that the sheer number and often remote location of small coffee farms raises questions about the ability of certifying agencies to guarantee that growers are complying with fair trade standards.

Sugar

Sugarcane was the first crop to be produced by Portuguese colonists in Brazil on a large scale. Since its introduction in the sixteenth century, sugar has remained an important export, and today Brazil produces around 25% and exports around 40% of the world's sugar. While sugar is produced from sugar beets in colder countries like the USA, sugar in Brazil comes from cane, which is milled shortly after harvest in the hundreds of mills concentrated in the central-south region of the country. The sugar industry employs over a million people and is responsible for 2% of the country's GDP. As global interest in biofuels grows, the market for Brazilian sugar (and ethanol) is booming. While the environmental and social controversies around sugar production have long histories, those debates are heating up as demand for ethanol surges worldwide.

Sugar was the economic engine of Portugal's very earliest colonies, and despite being displaced first by coffee and later by the growth of industrial agriculture, sugar has never fallen far from the top of Brazil's most cultivated crops. In colonial times, sugar production was concentrated in the northeast and central-south regions of the country where the tropical climate is conducive to its cultivation. The extant states of São Paulo, Paraíba, Pernambuco, Bahia, and Sergipe were the epicenter of sugarcane production during those times, but with the conversion of the *cerrado*, cane cultivation has spread rapidly and decisively to the west. With the increasing global demand for ethanol, sugarcane has once again begun to compete with soy, cattle, corn, and other industrial crops for valuable acreage. In fact, acreage planted to sugar almost doubled in Brazil between 2004 and 2010.

As with soy, much of this expansion has happened on what was formerly pasture land, and many argue that this only pushes cattle ranching

deeper into the Amazon region, resulting in deforestation. Ramping up production also means tougher working conditions for the (often migrant) laborers who cut cane. These issues are thrown into even sharper relief by the worldwide scramble to find an alternative liquid fuel for the global transport fleet.

Brazil has perhaps the oldest and best-developed ethanol industry and infrastructure in the world. The oil crisis of the 1970s prompted the Brazilian government to introduce a program called PROALCOOL, which provided incentives for the production and distribution of sugarcane ethanol as an alternative transport fuel (Borges 1990). Once the oil shock passed and gasoline prices dropped, the ethanol industry began to suffer. International sugar prices were on the rise in the 1990s, which made Brazilian ethanol less competitive in the consumer market. However, by this time the infrastructure was in place (many gas stations have two sets of pumps that dispense gasoline and pure ethanol), and government mandates to blend ethanol into gasoline kept the program alive. The invention of flexible fuel vehicles, which can run on gasoline, ethanol, or any blend of the two, significantly reinvigorated the industry, and by 2011, though only 4% of Brazil's light vehicle fleet had all-alcohol engines, flex-fuel engines were present in more than 50% of the existing fleet and in more than 90% of new cars sold (UNICA 2013). Despite falling short of domestic demand, Brazil exports a significant amount of ethanol, and the USA is the biggest customer. Import tariffs combined with a hefty subsidy for corn-based ethanol significantly limited Brazilian imports for decades. However, in 2012 the US congress suspended the 30-year-old subsidy and did away with the tariff in a single piece of legislation. The Environmental Protection Agency's mandate to blend more than 13 billion gallons of ethanol into all gasoline sold in the USA kept demand high and prompted significant imports from Brazil.

The ethical implications of the growing biofuels industry are well documented (Thompson 2008; Buyx and Tait 2011; Macer 2011; Shortall and Millar 2012). Many argue that it is unethical to devote farmland to fuel

production when so many in the world remain food insecure. In addition, the environmental benefits of biofuels versus fossil fuels are controversial, and biofuel production is driving foreign land acquisitions that some say threatened the food sovereignty of hungry nations. In some parts of Brazil, the march of sugar plantations is seen as a threat, both to the environment and to small farmers who compete with sugar producers for access to land. The controversies over sugar are perhaps only eclipsed by one even more ethically charged crop: soybeans.

Soy

In 2012, the soybean complex (beans, meal, and oil) surpassed iron ore to become Brazil's single most valuable export. Until the 1980s, soy production was concentrated mostly in the southern states and served primarily the domestic animal feed and cooking oil market. The central-west part of the country is today's soy epicenter thanks to the research of Embrapa (mentioned above) that rendered the *cerrado* soils suitable for agriculture and developed soybean varieties adapted to the subtropical climate of the region. The challenge of growing soybeans under these conditions continues because, although the seed can be inoculated with bacteria that allows the plants to fix nitrogen into the soil (thereby reducing the need for nitrogen fertilizers), the warm and wet conditions create a perfect incubator for fungus and insects that have taken up residence in the vast monocultures of soy. Producers must use increasing amounts of fungicides and insecticides to keep these threats at bay, and the long-term consequences of these chemical applications are unknown. However, so far, farmers have managed these problems, and soy continues to spread across the vast plains of the central-west. Within a decade of the first forays of soybeans into the *cerrado*, the central-western states of Mato Grosso, Mato Grosso do Sul, and Goiás and the westernmost part of Bahia were out producing the traditional agricultural centers in the south (Peine 2009). Today, Brazil is the world's largest producer and exporter of soybeans.

This dramatic expansion has brought economic growth and prosperity to both the

central-west and the country as a whole, but it has not happened without ethical controversy. The main critique leveled at the soybean boom is that it has been responsible for the dramatic expansion of deforestation in the Amazon and *cerrado* ecosystems. As Brazilian soybean production skyrocketed throughout the 1990s and early 2000s, the rate of deforestation in the Amazon region accelerated as well, reaching a record high of 10,722 mile² in 2004. While soy farmers argue that the majority of new land converted to soy farms is degraded pasture left behind by cattle ranchers and *not* newly deforested for the purpose of planting soy, environmental activists counter that this expansion of soy cultivation *pushes* cattle ranchers farther into the rainforest, indirectly contributing to both the release of carbon dioxide that results from burning and clearing land and also the loss of what is perhaps the largest "carbon sink" in the world.

Pressure from international environmental organizations prompted transnational agribusinesses to sign onto the Round Table on Responsible Soy (RTRS) in 2006. This voluntary agreement seeks to prevent the purchase of soy grown on land that was deforested after the year of implementation (among other provisions). While the direct impact of the RTRS on deforestation has not been measured, the trend in deforestation since its inception has been dramatic. In 2012, just 7 years after reaching a record high, the rate of Amazonian deforestation in Brazil fell to a record low: just 1798 mile².

Cattle

Anyone who has traveled to Brazil is familiar with the famous *churrascarias*, where waiters roam cavernous dining rooms bearing enormous skewers of different cuts of beef. Brazilians eat more beef per capita than consumers in the USA (lagging behind only Argentina), and 80% of the beef produced in Brazil is for the domestic market. In the USA, "grass-fed beef" is a niche product for those concerned about the animal rights, human health, and the environmental consequences of concentrated animal feeding operations, or CAFOs, which are the source of most of the beef, pork, and poultry in the US market. In

Brazil, however, most beef cattle graze on open pasture until slaughter, or with a short “finishing period” (on average about 7% of the total life span) in a feedlot. Cattle in the USA can spend up to a third of their lives in a feedlot. Because Brazilian cattle spend more time on grass and therefore grow more slowly, they are also usually around twice as old as their US counterparts at slaughter (Millen et al. 2011; USDA 2012).

Beef is a centerpiece of the Brazilian diet, and until the last decade, domestic production could barely keep up with demand. In 2003, however, Brazil overtook Australia as the world’s top beef exporter, and the largest beef processing company in the world – JBS – is a Brazilian company that began with just one slaughterhouse in 1953. Over the past decade JBS has acquired many of the world’s best-known meat companies (Swift, Five Rivers Ranch, and Smithfield Beef, among others) and has a slaughter capacity of 74,000 head a day in Brazil alone.

This significant and rapid growth in production has meant more land in pasture, but the productivity-to-area ratio has not been one-to-one. This is partly due to improved genetics in Brazil’s beef herd, but also because of the increased use of feedlots. Feedlots have made Brazilian beef production more efficient by providing an alternative to pasture during the dry season when cattle would otherwise lose weight (Steiger 2006). While only 4% of the 2011 Brazilian beef herd was raised in feedlots, many analysts predict that this strategy will become more common in the years to come, particularly as pressure to limit deforestation continues and demand rises for competing crops. The environmental trade-offs of feedlot versus pastured beef are certainly not straightforward. While the land pressure of grazing is clear, grain-fed cattle produce significantly more methane than pastured cattle. According to the US Environmental Protection Agency, the “greenhouse effect” of methane gas is much more severe than carbon dioxide, and agriculture – particularly beef and dairy cattle – is the main source of methane in the USA. Grass-fed beef is also leaner and richer in omega-3 fatty acids than grain-fed beef and is therefore often believed to be healthier. However, as mentioned above, global demand for beef is rising, and Brazil is

stepping up to meet that demand. Whether increased production happens on pasture or in feedlots, it will undoubtedly have important – and complicated – environmental implications.

Horticulture

Fruits and vegetables are one of the few agricultural sectors in Brazil where both small-scale and large-scale farmers work to serve both the export and domestic markets. Pineapples, peaches, grapes, cashew nuts, lemons, mangoes, melons, coconuts, papaya, and bananas are all economically important export crops for Brazil (though they may be dwarfed in total value by the behemoth sectors of soy, sugar, cattle, and coffee). Because the FFV (fresh fruits and vegetables) market is high value and tends to be more labor intensive, it is often seen as an important development strategy for small farmers in Brazil’s impoverished northeastern region. Although intense concentration in the retail food sector worldwide, increasing capital requirements of “high-tech” production, and stringent quality standards create barriers to entry into global markets for many small-scale producers, horticulture has been shown to be a more profitable sector for these farmers than commodity crops (Selwyn 2013).

The social, political, and market dynamics of the export grape industry in the São Francisco valley have been the subject of much scholarship (Selwyn 2009, 2013; Collins 1993; Bonanno and Cavalcanti 2011). The valley is located in what is known as the *sertão*, a traditionally drought-stricken area that has been transformed by extensive government investment in irrigation infrastructure. It serves as a rich case study of agricultural development because of the active role of the federal government in constructing, not just the physical infrastructure for irrigated agriculture, but also the social organization of farming for a specific political purpose. As Selwyn (2013) describes, the region was first transformed in the 1970s through damming and irrigation that disrupted traditional livelihood strategies and land tenure. The government redistributed land and provided irrigation services to encourage production for the domestic market as a strategy to combat food insecurity. Later,

when domestic food security faded as a concern and paying down international debt took its place as a major national priority, the government began to encourage production for the export market. This prompted a shift in the valley from basic food crops to high-value horticultural crops for the international market. This shift has had serious implications for land access in the region, and many small producers are forced to become farmworkers as a result of land consolidation. Today, more than 40,000 workers are employed in irrigated agricultural production, and the valley's main crops are mangoes, bananas, coconuts, and grapes (Selwyn 2013). Because the sector is so labor intensive, both jobs and workers' rights abuses are produced here. Perhaps the most visible social movement for rural workers' rights has occurred in Brazil's fresh grape sector.

Small-Scale, Family, and Subsistence Farming

As shown above, agriculture is big business in Brazil. However, the majority of the food that Brazilians eat every day still comes from smaller farms, and the 2006 Agricultural Census categorizes two thirds of Brazil's 4.1 million family farmers as "subsistence" (Berdegue and Fuentealba 2011). Small-scale farming is crucial for providing food, employment, and economic resources for Brazil's rural population, but small farmers often lack secure access to or tenure over the land on which they depend for their livelihoods. Since Brazilian independence, land tenure has been a politically volatile issue, as land ownership has historically been a prerequisite for citizenship (Wittman 2009). As the Brazilian countryside has been restructured as an export platform, those who still work the land for subsistence – and those who have been driven from the land for the sake of agricultural consolidation – struggle to secure their livelihoods in the face of marginalization and often outright violence. For the last 30 years, the Movimento dos Trabalhadores Rurais Sem Terra (the landless rural workers' movement, or MST) has been enacting grassroots land reform through land occupations with the aim of securing legal rights to otherwise "unproductive" land. The movement identifies land held by speculators or

absentee landlords and organizes landless families to occupy the land and put it into production. The constitution that was drafted after the end of the military dictatorship in 1988 declares that land must serve a "social function" or risk being expropriated by the government for the purpose of agrarian reform. The MST uses this provision as legal justification for its occupations and often is able to gain legal title to the land and establish permanent settlements. Since its inception, the MST has legally settled more than 370,000 families on 7.5 million hectares of land. There are 900 active encampments, with 150,000 people living in precarious conditions (MST 2013). The organization sees the current government of Dilma Rousseff as pro-agribusiness and indifferent to grassroots land reform. According to MST leadership, Rousseff's administration has "frozen" land reform in the interests of land consolidation for large-scale agribusiness (MST 2013).

As long as ownership of valuable farmland continues to be highly concentrated in the hands of a relative few, and as long as Brazil's rural population continues to struggle to provide for their own (and the nation's) food security on small plots of land for which they have no secure title, land conflicts will likely continue, and land politics will likely be a volatile and divisive issue.

Summary

Brazil is an agricultural powerhouse that has been profoundly shaped by the larger historical processes of colonialism, industrialization, and liberalization. Today, Brazil's agricultural sector is bifurcated; large-scale industrial producers of commodity export crops compete for land and resources with smaller-scale farmers growing food for the domestic market and their own subsistence. Of course, this dichotomy is an oversimplification of a much more complex and varied landscape that cannot be reduced to such discrete socioeconomic categories. Within each subsector, ethical, environmental, economic, cultural, and social issues present a challenge to policy makers, consumers, and farmers alike. Commodity crops like soybeans, sugar, coffee, and beef provide a

crucial economic resource and source of employment, but all are fraught with ethical controversies. The employment of slave labor on some large farms has foiled the federal government's attempt at eradication, and every year thousands of workers are "freed" from bondage. Because Brazil's agricultural frontier exists at the interstices of the cerrado and the Amazon, large-scale production of soy and sugarcane has become an environmental lightening rod. Finally, Brazil's peasantry is vibrant, productive, well organized, and unwilling to be cast aside for the sake of export growth. The ethical issues that arise over access to land promise to continue as global demand for Brazilian commodities intensifies. In short, Brazilian agriculture sits squarely at the intersection of some of today's most pressing ethical questions. How does society balance economic growth and environmental protection? How does society structure the food system to provide the best food for the most people at the lowest social, environmental, and economic cost? These questions will be addressed through policy and research, but also by grassroots social movements demanding equity and consumers demanding a healthier and more just food system. Brazilian agriculture stands as a bellwether for the future of food and agriculture around the world.

[Physiology of taste](#)

Introduction

Jean Anthelme Brillat-Savarin (1755–1826) is the author of *La Physiologie du goût* [*The Physiology of Taste*]. Appearing in Paris in 1825, this delightful record of a lifetime's observations has remained continuously in print, unrivalled as the core gastronomic text. While the book is more quoted than read and lacks an authoritative edition or analysis in either French or English, it provides a seemingly inexhaustible supply of insights that includes a hedonic theory of history.

La Physiologie du Goût

“Tell me what you eat, and I shall tell you what you are,” Brillat-Savarin is well known for

announcing. This is the fourth of twenty aphorisms that he intended “to serve as a prolegomenon to his work and as a lasting foundation to the science,” by which he meant gastronomy. The aphorisms announced an ontology: “The universe is nothing without life, and all that lives nourishes itself” (Aphorism I). They recommend hedonism: “The Creator, obliging people to eat to live, invites them through appetite, and compensates them through pleasure” (Aphorism V). This hedonism is bounded: “Those who stuff themselves or who intoxicate themselves know neither how to drink nor how to eat” (Aphorism X). It must also be shared: “To have invited someone is to take responsibility for their happiness for the whole time they are under our roof” (Aphorism XX).

The bulk of *La Physiologie du goût* comprises 30 meditations. Often described as disordered, the meditations follow a broad plan, namely: senses and taste (meditations 1–2); gastronomy (3); foods and drinks (5–9); end of the world (10); gourmandise (11–13); table pleasure (14–15); physiology – digestion, rest, sleep, dreams, dietary influences on these, obesity, treatment of obesity, thinness, fasting, and death (16–26); and history of cooking and culminating in restaurants (27–29). After “Bouquet” (30), which proposes a fanciful public ceremony in favor of a new, tenth muse, Gastérea, and a summary “Transition,” a collection of anecdotes, recipes, and poems under the heading “Varieties” conclude with a brief “Envoy to the gastronomers of the two [Old and New] worlds.”

The book is evidence in itself that meals lead to poetry, charming encounters, and fond memories. However, revealing “what you are” requires wide study: “To fulfil my self-appointed task, I had to be physician, chemist, physiologist, and even a little erudite” (Preface). Moreover, the “Preface” made clear that he spoke in two registers – conversationally and as a “professor” – so that he also left more formal findings on a range of topics that include obesity and death. More effectively than any other work, his book sets out a complete worldview grounded in meals and supported by a field of inquiry with its program, style, and method.

Arguably the work’s most systematic contribution is a hedonistic theory: that in the service of the *stomach*, the exceptional *taste ability* of humans has lent itself to the practice of pleasurable eating or *gourmandise*, which attracts the more complete *table pleasure* (incorporating not merely the physical pleasure of eating but the whole circumstances, including settings, memories, and conversations) and which drives the *political economy* that requires the *sciences*, the peak of which is *gastronomy*.

Brillat-Savarin devoted himself to meals in revolutionary times, politically, religiously, and intellectually (Teulon 1998). As food changed rapidly and the wider society and culture with it, facilitating the capacity of “the aesthetic pleasures of eating . . . to transform food into language” (McLean 2012, p. 50), so that he contributed greatly to gastronomy becoming its own cultural field (Ferguson 2001).

After a description of the author, the book, and its reception, this entry outlines Brillat-Savarin’s hedonistic argument. Section numberings accord with M.F.K. Fisher’s translation (and these numberings follow an anonymous translation in 1884; both remain identical with the first edition until the original §86, when they become one higher, after §119 two higher, and after §132 five higher; Anne Drayton’s translation is the same as a French edition [1923?], and these run one higher than the anonymous/Fisher numberings between §60 and §86).

Biography

Jean Anthelme Brillat-Savarin was born on 1 April 1755 in the attractive town of Belley on the edge of the Alps. He studied law and some medical subjects at Dijon University from 1774. A provincial lawyer elected to the National Assembly in 1789, he was mayor of his hometown in 1793, when forced to flee the Reign of Terror to Switzerland and eventually America, where he spent 2 years teaching French and playing violin in a theatre orchestra. Among other adventures, he transmitted knowledge of the *fondue* gained on the run in Switzerland to the smart French restaurateur in Boston, Julien,

who subsequently rewarded him by organizing a rump of Canadian roebuck (Varieties 13).

Returning to France in 1796, Brillat-Savarin was soon appointed a judge of the Court of Cassation in Paris, a position he held the rest of his life. He wrote on other matters, including books on public administration (*Vues et projets d'économie politique*, 1802) and duels (*Essai historique sur le duel*, 1819), but gastronomy was a long-term, secret project, although “more than one friend has already guessed your secret” (Dialogue). He published *La Physiologie du goût* at his own expense at the end of 1825 (dated 1826), and he died shortly after in Paris on 2 February 1826. His anecdotes reveal him to be well connected with the medical, scientific, and philosophical communities. He remained unmarried; biographer Giles MacDonogh (1992) reports that some decades later, his family destroyed records of liaisons.

La Physiologie du goût is a collection of bon mots, reports of findings, close observations, and theoretical sketches; he explicitly contributed “in the midst of these solemn meditations, a piquant anecdote, a pleasant memory, or some adventure of an active life” (§15). Virtually every commentator admits to being captivated by the wit, and he has been held up as a model stylist. For Charles Monselet, when introducing the book in 1879, Brillat-Savarin commanded the anecdote’s “real secret, elegance, and tone.” A meal is recalled with charm, science delivered with mock seriousness, and profundity delivered with puckish humor. Such features are illustrated in the touching prefatory “Dialogue between the author and his friend.” The friend (eminent physiologist Anthelme Richerand) entreated the author not to leave publication of so much labor until after his death. But people who only know the book by the title will think me trivial, responded the author, ultimately relenting, but only so that he could expose his friend’s sole vice. Pressed, Brillat-Savarin announced: “You eat too fast!” (Dialogue).

“Yet to see Brillat-Savarin solely as a stylist is to underestimate the philosophical depth of the work,” Michael Garval warns (2001, p. 659). Brillat-Savarin chatted about life’s imperatives – “The Creator has imposed on people six great and

principal necessities, which are: birth, activity, eating, sleeping, procreation and death” (§122). After contented sleep, a person “goes back to society without once regretting the lost time” (§98). Dreams usually lack taste and smell, so that we see feasts without tasting them (§87). As to the “end of the world,” he suggested filling idle moments by imaging what would happen if, say, a stray comet caused global warming. His only hint is that “real danger tears down all social ties,” as when husbands closed doors on their wives during a yellow fever epidemic in Philadelphia in 1792 (§54).

As an empiricist of the table, he observed the organs of taste, the psychology of the meals, and social conventions. Should coffee be pounded or ground in a mill? He purchased some good mocha, divided it into two samples, and tested the results on devout connoisseurs, who supported pounding (§46). The suspicion that the truffle contributed to sexual pleasures necessitated further, “undoubtedly indelicate” research. His respondents decreed: “The truffle is not a positive aphrodisiac; but it can, in certain situations, make women more tender and men more agreeable” (§44).

As a founding member of the Society for the Encouragement of National Industry, he demonstrated to the board his invention of the “irrorator” – a pocket pump for perfuming the air. With droplets raining, the learned heads bowed “under my irroration” (Preface). “Playing the scientist” – that’s how Roland Barthes depicts Brillat-Savarin; he took science “seriously and ironically at the same time; his project of founding a science of taste, of stripping culinary pleasure of its habitual trademark of futility, that was certainly heartfelt; but he carries it out emphatically, that is to say, ironically” (Barthes 1975, pp. 14, 28). For Brillat-Savarin, too, empirical studies of taste were merely the start, “for it is, above all, from its moral history that this restorative sense gains its importance and its glory” (§15).

Some scholars have argued that Brillat-Savarin plundered, without acknowledgement, from Grimod de la Reynière (1758–1837). Michael Garval sets sentences from Grimod alongside seven of Brillat’s aphorisms. Where Grimod had written: “A great dinner without hors d’oeuvres is

as valueless as a woman without rouge,” Brillat-Savarin decreed: “A dessert without cheese is like a beautiful woman missing an eye.” However, such quips and ideas do the rounds of dinner parties, and Garval concludes: “Grimod’s manic energy, his discoverer’s exuberance, lay the foundation for Brillat’s greater sobriety, maturity of judgement, and stylistic sophistication” (2001, pp. 60–61). Anticipating food journalism, Grimod’s gastronomy is more closely related to the now widespread marketing version – that is, to the promotion of high-quality products, retailers, restaurateurs, and regions – than to Brillat-Savarin’s ambitions for gastronomy to become a total, supervisory discourse.

A succession of important writers have introduced French editions, starting with his physiologist compatriot, godchild, and friend Richerand in the fifth edition of 1838, Charles Monselet in November 1879, Jean-François Revel in November 1981, and no more sustained interpretation is available than Roland Barthes’ to an abridged edition in 1975. The most devoted responder has been US writer M.F.K. Fisher (1908–1992). In her first book, *Serve It Forth*, Fisher wrote that *The Physiology of Taste* “is as near perfection as we yet know it, and a constant wonder.” Even better than quoting from it, she wrote, is “the companionship of the book itself.” She went on in 1949 to a greater tribute, her translation with copious notes (Brillat-Savarin 1971).

A neuroscientist examining flavor, Gordon Shepherd, dots his book with such statements as “Amazingly, Jean Anthelme Brillat-Savarin already knew this . . .” (2012, p. 125). Philosopher of taste Carolyn Korsmeyer is equally supportive: “The book . . . remains a worthy model of a study of taste that is serious yet light-hearted, moderate without moralism, speculative yet sensible. It is also a monument of its kind to what can be accomplished through amateur research and thoughtful introspection” (1999, p. 69).

The Core Argument

Brillat-Savarin left convincing testimony of the ethics of companionship, demonstrating the care

for others typical of a good meal. This companionship must be based on self-interest because, as he wrote, gourmandise motivates the great care taken by hosts, employing all their knowledge and tact, just as it stimulates the guests’ gratitude. Brillat-Savarin shunned “those stupid diners who swallow with culpable indifference the most distinguished morsels, or who inhale with sacrilegious inattention a fragrant and limpid nectar.” In turn, he advised encouraging others by expressing appreciation not merely of exceptionally intelligent arrangements but any attempt to please (§59). However, his etiquette of conviviality is not spelled out as consistently as his argument for meal-centered pleasure, which occupies the remainder of this entry.

From the title, the book concerns “taste.” However, it is about the “pleasure of the table,” he announced (Preface), and he also wrote with two purposes always before him – to redeem gourmandise and to establish gastronomy (Transition). In support of this last, the *Physiologie du goût*’s original subtitle was *Méditations de gastronomie*; it was dedicated to the *Gastronomes parisiens*; he signed off as the author of the “Méditations gastronomiques.” The compound word, “gastronomy,” spans from the most natural (*gaster* – ancient Greek for “stomach”) to the most cultural (*nomos*, “law”). In all, had gave prominence to the stomach, taste, gourmandise, the pleasure of the table, and the science of this, and these topics are considered here in turn.

While the stomach is basic and he assembled a “polite” depiction of ingestion and digestion (Meditation 16), the stomach is shared with other animals. The human species is marked by its exceptional taste abilities. Throughout the processes of chewing, including the tongue movements “of *spication*, of *rotation* and of *verrition* (verro, Latin, I sweep),” and swallowing, “there is not a single particle, a drop or an atom, which has been not been submitted to the appreciative power” (§14). From “direct” through “complete” to “reflective” sensation, taste aesthetics are sequential (§11), which Kevin Sweeney (2007) finds philosophically interesting, also noting how refined meals would soon shift from massed display (*service à la française*) to sequential (*service à la russe*).

Brillat-Savarin emphasized that the pleasure of taste is the only one that everyone can enjoy, possibly even two or three times a day, that can console for the absence of other pleasures, that is “not followed by regret,” and that is more lasting and more subject to our will; “finally, in eating we experience a certain indefinable and particular well-being, which arises from instinctive consciousness; that, by us eating, we replace our losses and prolong our existence” (§13).

The appreciative power of taste is the basis of gourmandise, which is “a passionate, considered, and habitual preference for whatever pleases the taste” (§55). He defined gourmandise with precision to distinguish this social grace once and for all from the “gluttony and intemperance with which it has for so long and so unfortunately been confused.” For zealous moralists have found excess when they could have found the “intelligent enjoyment of the earth’s treasures, which were not given to us to be trampled underfoot” (Transition).

Gourmandise in this other sense (“gluttony” in English) has remained a cardinal sin of the Catholic Church. To such strictures, Brillat-Savarin responded: “When gourmandise turns into gluttony, voracity, or debauchery, it loses its name, its advantages, and all its powers, and falls to the moralist, who can preach upon it or the doctor who can cure it with prescriptions.” He therefore asked any translator of his “instructive book” to use the French “gourmandise” (§59), so avoiding the misleading implications of the English “gluttony” and also showing respect for the French development of both “*La Coquetterie* and *La Gourmandise*, those two great improvements which extreme sociability brought to our most imperious needs” (§59 note).

Hedonism

The gourmand has a sacred trust, obeying the “rule of the Creator, who, having ordered us to eat in order to live, invites us to do so with appetite, encourages us with flavor, and rewards us with pleasure” (§56). People are to enjoy everything that the earth produces, he stated repeatedly.

It is for human beings that the quail fattens, that mocha (coffee) has a sweet perfume, and that sugar benefits health. Human beings are granted dominion, and so: “Why not take advantage, at least with appropriate moderation, of the good things which Providence offers, especially if we continue to accept that they are short-lived, especially if they excite our gratitude towards the Author of all things” (§66). Based on the epidemiological research of Dr. Villermet, who found that human mortality diminishes in direct proportion to the standard of living, “good living is far from being destructive to good health.” All other things being equal, “gourmands live much longer than other folk” (§68).

As well as responding to appetite, hunger, and thirst (§79), people could seek consolation in hedonism: “Humanity is incontestably, among the sentient beings that populate the globe, that which is inflicted with the most suffering.” People have unprotected bodies, poorly shaped feet, an inclination to war and destruction, and a mass of maladies such as gout, toothache, acute rheumatism, and strangury. The fear of all this pain makes people give themselves up to the “small number of pleasures which nature has allotted” (§70).

Engaging with all levels of reality, people experience full-blown “table pleasure” (*plaisir de la table*) (Meditation 14). “The pleasure of the table is the reflective sensation that arises from the various circumstances of deeds, places, things, and people that accompany the meal.” That is, on top of being blessed with a relatively intense experience of taste, human beings use their other senses and also enjoy company, not least through conversation. Brillat-Savarin carefully distinguished between the pleasure of *eating* and the more comprehensive pleasure of the *table*. Unlike eating pleasure, table pleasure is largely independent of the drive for food; it is a *reflective* pleasure known only to the human race (§72). This relates to his distinction that “Animals feed; people eat; only those with wit know how to dine [*l’homme d’esprit seul sait manger*]” (Aphorism II).

Under the influence of table pleasure, the diner’s brain is refreshed, the face lights up, color heightens, eyes shine, and a “sweet warmth” spreads through the body. It is far from a mere physical pleasure,

since also, morally, the diner's spirit grows more perceptive, the imagination flowers, and clever phrases fly from the lips. "Effectively, as the result of an appreciated meal, both body and soul enjoy a special well-being" (§73).

Brillat-Savarin listed twelve requirements for peak table pleasure. The maximum number of guests should be 12, so that conversation may remain "general" (everyone sharing the one thread). The room temperature should be between 13 and 16° Réaumur (around 60–68 °F). The progression of dishes should proceed from "the most substantial to the lightest" and so on. But that was for fashionable dinners, and Brillat-Savarin often preferred simplicity. So, the minimum requirements for table pleasure are passable food, good wine, amiable companions, and sufficient time. The most careful preparations and sumptuous accessories are to no avail "if the wine is bad, the guests gathered without discretion, the faces glum, and the meal consumed in haste" (§75).

English translators have rendered *plaisir de la table* mostly as the plural "pleasures of the table." Yet positive sensations, memories, and ideas and feelings of togetherness come together as a single *table pleasure*. As Roland Barthes explains, Brillat-Savarin observed that pleasure was "*over-determined*, that it must have multiple simultaneous causes." He taught the value of "composite pleasure" [*plaisir composé*] and so "composite histories" [*histoires composées*] (Barthes 1975, pp. 30, 33).

Hedonic Theory of History

Gourmandise drives the economy because, firstly, it "sustains the hopes and ambitions and performances" of fishers, hunters, horticulturists, and such. Secondly, appetites provide the "livelihood of an industrious multitude of cooks, pastry cooks, confectioners, and other preparers of food," who, thirdly, "employ still more workers of every kind." Gourmandise becomes "the common bond which unites peoples through the reciprocal trade of goods serving daily consumption." Any industry aimed at gourmands is aimed at both the "fattest fortunes" and the "commonest daily

human needs." All of this causes an inestimable "flow of capital" (§55).

As an example, following Napoleon's defeat at Waterloo in 1815, the victorious nations extracted reparations. Rather than collapse, however, the French economy prospered. "What power came to our aid? What divinity worked this miracle? Gourmandise." Before long, "the queen of cities was no more than an immense refectory. These intruders ate in the restaurants, in the cookshops, in the *cabarets*, in the taverns, in the street stalls, and even in the streets." Among the food businesses, restaurateur Véry increased his fortune, *pâtissier* Achard began his, restaurateur Beauvilliers made a third lucky one, and Madame Sulot sold 12,000 of her tiny tarts a day from tiny shop in the Palais-Royal (§57).

The relatively lengthy Meditation 27 outlines a gastronomic theory of history: "all human industry has been concentrated on augmenting the duration and intensity of table pleasure." Since throats and stomachs have limits, people threw themselves into improving the accessories. So, they ornamented goblets and vases, invented the charms of music, and sprayed exquisite perfumes. Dancers, clowns, and other entertainers amused the eyes, every sense joined in a comprehensive pleasure of the table (§74). To such ancient gratifications, his recent contemporaries contributed dishes that were so delicate that people would never have to get up from table except that other business intruded (§75). Historically, the increasing sophistication of the economy culminates in restaurants (§136).

Brillat-Savarin's history of the sciences can be understood in this context, each new science pushing the limits to human powers in catering to gourmandise. He appreciated that the sciences were freed from "the danger of regression" when they were at last captured in print (§15–17), and the sciences at last made way for gastronomy.

Gastronomy

Starting with the imperious needs of the stomach, the dutiful actions of the tongue and the exceptional god-given taste abilities, the book explains

how civilization evolved to cater to gourmandise through the political economy and the sciences, until a “new science has suddenly appeared that nourishes, restores, preserves, persuades, consoles and, not satisfied with strewing armfuls of flowers in the path of individuals, contributes even more powerfully to the might and prosperity of empires” (§15). This new science is gastronomy (Meditation 3).

Brillat-Savarin defined: “*La gastronomie est la connaissance raisonnée de tout ce qui a rapport à l’homme, en tant qu’il se nourrit,*” which translates as the “systematic knowledge of everything that relates to human beings so much as they nourish themselves.” He went on: “Its purpose is to watch over the preservation of people by means of the best nourishment possible.” It rules over the entire lifespan from the cries of the newborn to the dying person’s final drop, which gives pleasure while being, sadly, too late to digest. It also looks after every social class, directing the banquets of assembled monarchs and prescribing the minutes to boil an egg (§18).

Note the “everything” in his definition, and he specified that gastronomy encompasses natural history, physics, chemistry, cookery, business, and political economy (§18). According to Barthes, “B.S. understood very well that as a subject of discourse food was a sort of grid (or topos, the classical rhetorician would have said), through which one could successfully pass all the sciences that we today call social and human.” In other words, food is a “total social fact around which a variety of metalanguages can be gathered: physiology, chemistry, geography, history, economics, sociology, and politics (today we would add the symbolic)” (1975, p. 32).

Rare in ancient Greece, the word gained currency following Joseph de Berchoux’s poem *La Gastronomie* in 1801. The revived word, Brillat-Savarin said, was not always understood, but put a merry smile on every face (§36).

Summary

Among the many contributions of the foundational text of gastronomy, *La Physiologie du*

goût, Brillat-Savarin set out a hedonic theory that makes the pleasure of the table the driving force of history and so the sciences, of which the culmination has been gastronomy. Given that the scope of gastronomy is often restricted to the promotion of particular items, styles, and regions of food, the intellectual fate of Brillat-Savarin’s work remains tied to the success of the discipline in its more ambitious version.

Introduction

The story and teachings of Buddhism entail multiple points of focus on food and eating. In addition to advocating for what foods are eaten, Buddhist teachings illustrating how food is prepared and consumed offer important guidance of the application of Buddhist principles to daily life. One principle example of Buddhist writing focused on cooking and eating is the writing of the thirteenth-century Japanese monk, Dōgen, who described how food preparation was an important opportunity for practice for monastic cooks in the Zen tradition or *tenzo*. Perhaps the most significant point of ethical consequence related to eating, and a topic of much debate among Buddhist practitioners, is the question of adherence to a vegetarian diet. Historically, this debate has centered on its relationship to the first precept for both lay and monastic practitioners – “do not kill” – and the value for not harming animals.

Elaboration of Key Principles in Buddhism

Story of the Buddha

Siddhartha Gautama was born into the noble Sakya clan near the city of Benares in northern India in around 560 BC. His early life is described as one of very good fortune, luxury, and opulence (Burt 1982). Yet, the young Siddhartha was unsettled with his position, and he questioned whether worldly pleasures of wealth, power, and luxury were truly the foundations of happiness. Having been purposefully sheltered from the vexations of life (old age, illness, suffering, death) by his father, Siddhartha knew nothing of these things until he managed to escape from the palace on several occasions. Each time, he observed a different form of suffering (an old man, a sick man, and a putrefying human corpse). Having perceived the impermanence of bodily pleasures and the inevitability of death and decay, he made a final escape from the palace to go into the world and seek the path to the true happiness of enlightenment.

The story of Siddhartha's spiritual journey involves his experimentation with several types of accepted practices of the day, particularly asceticism and yoga (Conze 2003). His practice culminated with austere eating to the point of living on, depending on the version of the story, a single bean, a single sesame seed, or a single grain of rice per day, until he fainted while crossing a river, nearly drowning had it not been for the presence of his spiritual companions. There is lack of consensus as to who cared for him after he fainted (Burt 1982), but the story of The Golden Bowl describes how a young woman named Sujata fed the starving man a pudding of milk and rice that she had made and he soon regained his strength. It was this intake of food that he credited with the rejuvenation of his stamina, allowing him to sit under the Bodhi tree until his enlightenment (Conze 2003; Buddha Dharma Education Association 2012).

In the story of his life, food illustrates Siddhartha's rejection of the excesses of decadence and self-indulgence, as well as his denial of deprivation or austerity, as viable means to enlightenment. This represents one aspect of the foundational principle of "The Middle Way," which Siddhartha Gautama ("The Buddha") described in his first post-enlightenment sermon (Burt 1982). In this way, eating only what the body needs – neither excess or indulgence nor denying the body adequate sustenance – becomes an opportunity for Buddhist practice.

Just as the story of Sujata marks the beginning of Siddhartha's time as the awakened one – "The Buddha" – food also plays a role in the end of his life. According to the *Mahāyāna Mahaparinirvana Sutra* of the Pali Canon, at approximately the age of 80 years old, the Buddha ate his last meal, which was an offering made to him by a metalworker named Cunda (Yamamoto and Page 2007). There is discrepancy in earlier scriptures and later translations as to whether the Buddha consumed tainted pork or poisoned mushrooms (Burt 1982). The sutra describes the Buddha as being afflicted by "dysentery, and he suffered sharp and deadly pains" (*Mahaparinirvana Sutra*, verse.21, Yamamoto and Page 2007). Shortly after that meal the

Buddha died, but before dying he asked his companion Ananda to deliver the following message to Cunda, lest he feel negatively responsible for the Buddha's death.

It is a gain to you, friend Cunda, a blessing that the Tathagata took his last alms meal from you, and then came to his end. For, friend, face to face with the Blessed One I have heard and learned: 'There are two offerings of food which are of equal fruition, of equal outcome, exceeding in grandeur the fruition and result of any other offerings of food. Which two? The one partaken of by the [Buddha] before becoming fully enlightened in unsurpassed, supreme Enlightenment; and the one partaken of by the [Buddha] before passing into the state of Nibbana in which no element of clinging remains. By his deed the worthy Cunda has accumulated merit which makes for long life, beauty, well being, glory, heavenly rebirth, and sovereignty.' (*Mahaparinirvana Sutra*, verse.56, Yamamoto and Page 2007).

Buddhist Practice

After the Buddha's death, a series of splits occurred in the community (Pāli – *Sangha*) for reasons of differing philosophy and geography; the result being that today, there are many sectarian divisions of Buddhism practiced around the world (Lopez 2001). Scholars of Buddhism distinguish three schools, also referred to as the "Three Vehicles" of practice into which all practices fall. All schools are believed to have their origins in India. Theravāda ("The Ancient Teaching") is the oldest and, comparatively, the most conservative school. It is also known as *Hīnayāna* or "Small Vehicle" practice as, on the surface, it is concerned mostly with self-enlightenment. This is the style most predominantly practiced throughout South East Asia and Sri Lanka. However, as with all styles of Buddhism, practitioners can be found around the world. Mahāyāna Buddhism ("Great Vehicle") is the largest of the divisions with variant styles found in many parts of the world – Zen in Japan, Pure Land and Nichiren in China, and Tibetan lineages. In Mahāyāna, practice emphasizes universal enlightenment and altruism, as illustrated through the *bodhisattva* principle of striving to attain enlightenment to benefit all

beings (Lopez 2001; Gyatso 2007). The third school, Vajrayana (“the Diamond Vehicle”), also known as *Tantric*, is associated with Mahāyāna practice and stresses ritual and a comparatively rapid path to enlightenment (Ray 2000). It also has its origins in India and Tibet, where the highest concentration of today’s practitioners are found.

The original teachings of the Buddha (Pāli – *Sutras*) are compiled into one triplex canon known as the Pali Canon (first century BCE) or *Tripitaka* (“Three Baskets”), which are central to all styles of practice and form the single text of the Theravādan school. Mahāyāna doctrine also includes more recent scriptures (Chinese Canon [983 CE] and Tibetan Canons [1411 CE] as well as other later translations of the Buddha’s original teachings (Pali Text Society 2012).

The three parts of the Pali Canon are the *Vinaya Pitaka* (“Discipline Basket”), which addresses rules for monks and nuns; the *Sutta Pitaka* (“Discourses Basket”) contains the discourses of the Buddha and some of his disciples, and the *Abhidhamma Pitaka* (“Higher Teachings Basket”) describes concepts and states pertaining to metaphysics and psychology.

Many of the points of debate pertaining to dietary restrictions in Buddhism arise from inconsistencies and variant interpretations between earlier Pali Canon discourses (Theravādan) and later Mahāyāna scriptures (Chinese and Tibetan Canons, in addition to other Mahāyāna literature) (Gunasekara 2012; Kapleau 1981; Kahila 2012).

Basic Tenets of Buddhism

To understand how Buddhism approaches food and eating, it is important to be familiar with the most basic Buddhist teachings, which are The Four Noble Truths, the Eightfold Noble Path, and its related Precepts for practitioners.

After his enlightenment, the Buddha gave his first teaching or discourse on the nature of suffering (Pāli – *Dukkha*) in his famous “Sermon at Benares” (Burt 1982). In this teaching, the Buddha outlined the foundational tenets of Buddhism called the “Four Noble Truths,” which are the following: (1) Living involves unavoidable cycles of suffering (birth, old age, sickness, and death)

(Sanskrit – *Samsāra*). (2) Suffering and remaining trapped in cycles of *Samsāra* (via reincarnation) are rooted in selfish craving, attachment, and comfort seeking (the “Three Poisons” [Pāli – *akusala-mūla*] of greed, hatred, and ignorance). (3) The only way to avoid suffering is to relinquish selfish craving and greed. (4) The way to do this is to follow the Eightfold Noble Path. This is the means to abolish suffering and free oneself from endless cycles of *Samsāra* (KHEMA 1987).

The Eightfold Path provides summary guidelines for psychological and moral orientations, as well as meditation practice. Couched within the Noble Eightfold path are the five (monastics follow many more) precepts, guidelines, or commitments for practice (Pāli – *pañca-sīlāni*) that are foundational to both Theravāda and Mahāyāna practice (Gyatso 2007). The Precepts are guidelines that facilitate practice, rather than rules that prompt rewards or sanctions.

It is the first of these precepts – the vow to abstain from taking life (“do not kill”) that has played the most significant role in Buddhist discourse about food, namely, the issue of vegetarianism. Unlike the Abrahamic religions (Judaism and Islam), the Buddha established few dietary laws (Wijayaratna 1990). According to the *Vinaya Pitaka* of the Pali Canon, this is limited to the explicit prohibition for monastics from consuming horses, elephants, snakes, lions, and dog, which implies that other meats were allowed. Monks were also forbidden from requesting favorite foods in alms, an indication of self-indulgence:

If a monk, who is not unwell, requests and eats delicacies such as curd, fresh butter, sesame oil, honey and molasses, fish, meat, and milk, he commits a Pacittiya offense. (Vinaya Pitaka, IV 88, Wijayaratna 1990)

However, how a practitioner engages with food is one component of the application of Buddhist principles, such as nonviolence (Sanskrit – *Ahimsa*) and the relinquishment of greed and ego gratification via the Eightfold Noble Path. In this way, the Buddha provided recommendations not only for what to eat but also how a practitioner should use food to facilitate practice of the “Middle Way” and skillful means (Sanskrit – *Upaya*).

Sōtō Zen: Dōgen and Instructions for the Zen Cook

Perhaps the most extensive discourse on the use of food for Buddhist practice comes from the Mahayana tradition and the thirteenth-century monk and founder of the Sōtō Zen school of Buddhism, Dōgen. He wrote detailed instructions for food preparation and consumption for monastics in his *Tenzo Kyokun* (Instructions for the Zen Cook), which was translated and commented upon by Kosho Uchiyama Roshi as the *Jinsei Ryori no Hon* (How to Cook Your Life) in 1970 (Dōgen and Uchiyama 1983). Together these works illustrate the principles of Buddhist spiritual training; maintaining equanimity, an unbiased mind, and *Upaya* through the daily tasks and processes of food preparation carried out by monastic cooks:

A dish is not necessarily superior because you have prepared it with choice ingredients, nor is a soup inferior because you have made it with ordinary greens. When handling and selecting greens, do so wholeheartedly, with a pure mind, and without trying to evaluate their quality, in the same way in which you would prepare a splendid feast. The many rivers which flow into the ocean become the one taste of the ocean; when they flow into the pure ocean of the dharma there are no such distinctions as delicacies or plain food, there is just one taste, and it is the buddhadharma, the world itself as it is. (p. 13)

Dōgen describes the role of the *tenzo* as being “the incomparable practice of the Buddhas” (p. 12) and an important opportunity for Zen practice. He states, “Though a person might be fortunate enough to be appointed to the office of *tenzo*, if he lacks the aspiration to walk the Way, he will return empty-handed from the mountain of goodness and the ocean of virtue” (p. 15). Dōgen describes the role of *tenzo* as being an experience that all potential monastic leaders should first undertake.

Dōgen also influenced how food is consumed in Zen practice, as he is also credited with bringing the practice of Ōryōki from Chinese monasteries to Japan, thereby introducing it to Zen practice. The practice of Ōryōki emphasizes mindful attentiveness to the act of eating through a ritualized series of movements and a specific process of eating and

completing the meal that acknowledge gratitude and attention toward the food (Loori 1999). Throughout the process, practitioners are called upon to focus attentiveness to the precision of each movement, as well as noticing distractions or wandering thoughts. In this way, mindfulness and self-awareness are fostered. The name Ōryōki translates to “just enough” in reference to the practice of not using more food or dishes that are left as waste or to clean for others, thus reiterating the principle of moderation and the “Middle Way.” The use of Ōryōki as a meditation technique has been adopted by other styles of Buddhist practice (Shambala 2012).

Buddhism and Food: What to Eat

Vegetarianism

The most prominent dietary practice, and question of ethical debate, pertaining to Buddhism has to do with vegetarianism. According to the *Tri-pitaka*, the Buddha was not a vegetarian. Nor did he explicitly advocate for a vegetarian diet (Gunasekara 2012; Kapleau 1981). However, the first of the precepts forbids killing and in the *Jivaka Sutra* of the *Majjhima Nikaya* (*Sutta Pitaka*) the Buddha prohibits his monks from consuming flesh from any animal that was “seen, heard, or believed” (referred to as the “Three-Fold Rule”) by the monk to have been killed specifically for his benefit (Nanamoli and Bodhi 1995; Gunasekara 2012; Wijayaratna 1990). The Buddha’s non-compulsory stance on food restrictions is illustrated in the *Khandhaka* or second book of the *Vinaya Pitaka*, via Theravādan portrayal of the story of Devadatta who was a clansman and fellow practitioner of the Buddha (Batchelor 2010; Wijayaratna 1990). The story describes how Devadatta challenged the Buddha’s leadership, including attempts at murdering him, and creating a schism among the Buddha’s followers. Devadatta insisted that the Buddha impose rules or “the Five Austerities” (Sanskrit – *Tāpasya*)” for the monks’ practice. Among these austerities were the requirements that monks should only live on collected alms and never accept invitations to dine with lay people. Devadatta also insisted that monks should abstain completely from eating any

flesh or fish and practice complete vegetarianism. The Buddha chose to allow the monastics to practice these austerities if they wished, but he did not impose them as mandatory (Nanamoli and Bodhi 1995; Gunasekara 2012).

The Buddha also cautioned his monks to accept alms without discrimination for a few reasons (Kahila 2012; Gunasekara 2012). First, if a monk refused alms based on dietary restrictions, lay practitioners would be prevented from gaining merit through their acts of charity. Additionally, as an application of the Buddha's prescribed "Middle Path," monks were counseled to eat all foods that they received as a practice of gratitude, humility, and given the Buddha's resistance to asceticism, to maintain a healthy body to support their practice (Gyatso 2007).

Most of the emphasis on vegetarianism stems from later Mahāyāna scriptures, such as the *Lankavatara Sutra*, *Brahma Net Sutra*, or the *Shurangama Sutra* in the Chinese Canons that take a stronger position on dietary practices than those originally attributed to the Buddha in the *Tripitaka*. For example, the *Brahma Net Sutra* states as one of the 48 Secondary Precepts:

3. On Eating Meat

A disciple of the Buddha must not deliberately eat meat. He should not eat the flesh of any sentient being. The meat-eater forfeits the seed of Great Compassion, severs the seed of the Buddha Nature and causes [animals and transcendental] beings to avoid him. Those who do so are guilty of countless offenses. Therefore, Bodhisattvas should not eat the flesh of any sentient beings whatsoever. If instead, he deliberately eats meat, he commits a secondary offense. (*Brahma Net Sutra: Moral Code of the Bodhisattvas* 2000)

Hence, Mahāyāna practitioners are more likely than Theravada, to practice vegetarianism, though there are many exceptions, particularly of Theravada practitioners following vegetarian diets (Kieschnick 2005).

In the Mahāyāna view, vegetarianism reflects the value of *Ahimsa* (nonviolence), which possibly also reveals an influence of Hinduism. The belief in reincarnation, which is foundational to Buddhism and Hinduism, might also play a role in the decision not to eat meat, given that, in this view, animals and

humans exchange incarnations throughout the cycles of *Samsāra* (Balsys 2004).

Given the above points, it is possible that, since followers of the living Buddha were mendicants who relied on alms begging and invitations to dine in lay practitioner's homes, the debate over vegetarianism probably did not arise until monks settled in monastic dwellings, whereby, if meat was provided to them by lay practitioners, it was most likely specifically killed for the monks' consumption (Kahila 2012).

The point of debate lies in the relationship of meat consumption to indirect or proxy participation in the killing of an animal; a violation of the first precept, and this is where the debate lies to this day (Kapleau 1981). The Australian monk, Venerable Shravasti Dhammika, points out that the principles of *Ahimsa*, not killing, and not contributing directly to the suffering of other sentient beings (e.g., animals) are a fairly straightforward argument though perhaps overly simplistic (Dhammika 2009). He illustrates the complexity of the debate by summarizing the following arguments on the side of meat-eating:

- (1) If the Buddha had felt that a meatless diet was in accordance with the Precepts, he would have said so and in the Pali Tipitaka at least, he did not.
- (2) Unless one actually kills an animal oneself (which seldom happens today) by eating meat one is not directly responsible for the animal's death and in this sense, the non-vegetarian is no different than the vegetarian. The latter can only eat his vegetables because the farmer has ploughed the fields (thus killing many creatures) and sprayed the crop (again killing many creatures).
- (3) While the vegetarian will not eat meat he does use numerous other products that lead to animals being killed (soap, leather, serum, silk, etc.). Why abstain from one while using the others?
- (4) Good qualities like understanding, patience, generosity and honesty and bad qualities like ignorance, pride, hypocrisy, jealousy and indifference do not depend on what one eats and therefore, diet is not a significant factor in spiritual development.

The Five Pungent Spices

According to Mahāyāna texts, such as the *Shurangama Sutra*, another precept – the Third

Precept – calls on the practitioner to exercise “sexual responsibility” (KHEMA 1987), which has significance for dietary practice, namely, in the avoidance of the “Five Pungent Spices,” which include leek, onion, garlic, and asafetida. Again, included in the 48 Secondary Precepts:

Beings who seek samadhi should refrain from eating [the] five pungent plants of this world. If these five are eaten cooked, they increase one’s sexual desire; if they are eaten raw, they increase one’s anger. (Shurangama Sutra, BTTS, 2002)

Avoidance of these spices is not, by and large, a practice of Theravadan Buddhists, as this dietary proscription is not recorded in the Pali Canon.

Summary

Many aspects of Buddhist practice reference food: from the start and end of Siddhartha Gautama’s spiritual enlightenment to guidelines crafted centuries later by monks to the debate over vegetarian eating. The Pali Canon is the text that contains the original teachings of the Buddha. There are few dietary proscriptions in this text, though many recommendations pertaining to eating have been added in later Mahayana writings. The Buddha’s advisement to his disciple Ananda that “decay is inherent in all compound things. Work out your own salvation with diligence” (Burt 1982, p. 22) illustrates a foundational orientation toward proscriptions in practice (including those pertaining to food) that the decision to adhere or not adhere has no other worldly ramifications, but only limits one’s own advancement toward liberation.

Buddhist Perspectives on Food and Agricultural Ethics

David R. Loy
Boulder, CO, USA

Synonyms

[Buddhism and GM food](#); [Buddhism and vegetarianism](#); [Food and dukkha](#) or “suffering”

Introduction

The variety of Buddhist traditions makes it difficult to generalize about its food and agricultural ethics. Buddhism as a missionary religion has tended to adapt to local dietary customs, rather than import food restrictions. Another factor encouraging this variety is that Buddhist traditions have often been less concerned about what we eat than how we eat it, since the *dukkha* (suffering or “dis-ease”) that it addresses is rooted in our craving – and food is the second most popular example of human craving. One persistent factor, however, has been a concern to reduce the suffering of animals, which contributed to the development of vegetarianism in East Asia. In general, Buddhism does not emphasize “being natural,” but its emphasis on intentions raises questions about the economic motivations for genetically modifying food.

Traditional Buddhist Perspectives

There are some important distinctions within Buddhism that have had important implications for food practices, especially the difference between monastics and laypeople, and the difference between Theravada (South Asian) and Mahayana (mostly East Asian) Buddhism. Monastics, following the personal example of the Buddha, are expected to live a simple life largely unconcerned about mundane matters such as food. In Theravada Buddhist societies, they eat only before noon (and usually only once). According to the *Patimokkha* rules that regulate their daily lives, “There are many fine foods such as these: ghee, butter, oil, honey, molasses, fish, meat, milk, and curds. If any *bhikkhu* who is not sick should ask for them and consume them, it is an offense entailing expiation” (*Vinaya Pitaka* IV. 88, in Oldenberg, 167). The careful wording implies that the problem is not with these foods themselves, but that desiring them and indulging in them is a distraction from what monastics should be concentrating on. There is no suggestion that lay followers should also avoid them, and the qualification – “any *bhikkhu* who is not sick” – exemplifies the pragmatic Buddhist approach: there may be times when even monastics would benefit from consuming them.

The main food issue for Buddhists has been, and continues to be, whether one should be vegetarian – somewhat complicated by the (contested) fact that, according to the earliest accounts we have, the *Mahaparinibbana Sutta*, Shakyamuni Buddha died of a stomach ailment caused or aggravated by eating pork. Buddhist vegetarians have sometimes considered this fact scandalous and denied it, but it is consistent with what is known about the early Buddhist community.

According to the *Vinaya* rules established and followed by the Buddha himself, Theravada monastics are mendicants. They do not grow or normally cook their own food; they beg for it. Being dependent on what is donated to them each morning, they are not required to be vegetarian, with two important restrictions. First, ten kinds of meat are prohibited, usually translated

as bear, lion, hyena, tiger, panther, elephant, horse, serpent, dog, and human flesh – but not including beef, pork, or fowl, the types of meat most commonly eaten (*Vinaya Pitaka* VI. 23, in Oldenberg, 193). Significantly, the prohibition seems to involve more concern for the social or physical consequences for the monks themselves than for the animals eaten (Kieschnick, in Sterckx 2005).

The other restriction is often followed by Buddhist laypeople as well as *bhikkhu*: not to eat meat (or fish) if you know or have reason to suspect that it was killed *for you*. “If a bhikkhu sees, hears or suspects that it has been killed for his sake, he may not eat it” (*Mahavagga, Vinaya Pitaka*, in Oldenberg, 220).

This would seem to be a compassionate policy, given Buddhist emphasis on not harming living beings. However, the issue of animal suffering is cited in Buddhist texts less often than the consequences for one’s own suffering: it is bad karma to cause the death of any sentient being. Even when those texts mention the importance of compassion, the main concern is often the negative effects of meat-eating on one’s own capacity to cultivate compassion (Kieschnick 2005).

Recently there has been a movement among expatriate Tibetan Buddhists (most of whom now live in the more tropical climate of India) to become more vegetarian, led by the Dalai Lama (who nevertheless sometimes eats meat for health reasons). This development is more consistent with a general Mahayana emphasis on vegetarianism, a concern especially strong in China and doctrinally supported by later Mahayana scriptures such as the *Lankavatara Sutra*, the *Surangama Sutra*, and the *Brahma’s Net Sutra*. The main points these texts make (e.g., Suzuki 1932) in favor of vegetarianism are that eating meat:

- Was prohibited by the Buddha (according to the *Lankavatara*)
- Is inconsistent with the first Buddhist precept, which prohibits taking the life of any sentient being
- Produces bad breath and foul smells that inspire fear in other beings

- Inhibits compassion and causes suffering to animals
- Prevents progress in Buddhist practice and causes bad karma (e.g., you might be reborn as a lower animal)
- May be eating a former relative

In the sixth century Chinese Buddhism (unlike South Asian Theravadin Buddhism) began to emphasize vegetarianism. Chinese, Korean, and Vietnamese monastics today continue to abstain from meat and fish (often milk products and fertilized eggs too), and many devout Chinese laypeople are also vegetarian. The laity played a leading role in this transformation: under the influence of Mahayana scriptures such as the ones mentioned above, as well as popular stories about karmic retribution, laypeople came to expect monastics to uphold higher standards of purity and renunciation. By the tenth century vegetarianism had become a minimum standard to be followed by all monks and nuns in China. As in South Asia, monastics are dependent upon lay support, so the concerns of an increasing number of lay vegetarians could not be ignored (Kieschnick 2005).

The only other important and common dietary prohibition is to avoid the five “pungent odors,” usually translated as garlic, onions, scallions, shallots, and leeks (sometimes chillies and other spices are added to this list). In addition to the often-objectionable smells associated with them – a big concern in a crowded monastic situation – the *Surangama Sutra* claims that they are stimulants to anger if eaten raw and stimulate sexual desire when cooked.

Two points should be kept in mind regarding the above dietary restrictions. First, although monastics in principle have no choice, laypeople choosing to follow them make a personal decision, in the sense that such practices are not required in order to be a Buddhist or follow the Buddhist path. Not observing them may create bad karma and make one’s spiritual path more difficult to follow, but that is one’s own decision. Second, as mentioned earlier, the key to Buddhist self-cultivation is less the “outer practice” of what one does than the “inner path” of how one does

it. This is especially emphasized in Mahayana, which has a more relaxed attitude toward such observances. *Upaya* “skillful means” may sometimes prompt us to break precepts in some situations, because Buddhist rules, like other teachings, are pragmatic rather than absolute. A moral mistake is not an offense against God but an unskillful act that causes more trouble for ourselves. Precepts are vows I make to oneself, that I will try to live in a certain way, with the understanding that when I fall short then I will bear the karmic consequences. This encourages a flexible attitude toward food practices.

Genetically Modified Food

Some contemporary Buddhists and Buddhist organizations have become concerned about food with genetically modified ingredients. For example, according to a December 1996 press release of the Dharma Realm Buddhist Association (based in Burlingame, California), “Genetic engineering of food is not in accord with the teachings of Buddhism. Genetic engineering of food is unwarranted tampering with the natural patterns of our world at the most basic and dangerous level.”

There is, however, virtually no support for the view that “unnatural is bad” in any important traditional Buddhist text, because Buddhism has not valorized nature or “being natural” in the way that the West has often done (although an exception is addressed below). For example, Asian Buddhist attitudes toward stem cell research are usually quite positive, according to “No Buddhist Hard Line on Stem Cells,” an article in *Science & Theology News*:

While many Buddhists in the Western countries view any destruction of embryonic life as wrong regardless of the possibility that a cure for severe diseases like Alzheimer’s or critical spinal cord injuries might be found in a distant future, a considerable amount of Asian Buddhists come to a more permissive conclusion. First of all, *Buddhists are not inclined to see a man-made creation as something competing with a “good” nature*. There is a very positive attitude toward changing

nature’s course if it enhances the welfare of all living beings, and more so if it allows medical advancements.

Second, *Buddhist ethics are not principles to be followed as law*. They are not designed as expressions of indisputable human rights or as a consequence of dignity inherent in every human being. Ethics are much more a matter of personal choice; principles like the one of “non-harming” should be followed as guidelines, and in extraordinary circumstances need not be applied in the strictest sense (Schlieter 2004).

Although food is not the issue addressed in this article, its implications apply to GM food as well. Buddhism generally has had a nonnormative understanding of nature, which does not appeal to “natural law” or some similar standard that must be observed. According to Lambert Schmithausen’s examination (1997) of ecological ethics in the early Buddhist tradition, the early texts emphasize the beauty of nature less than the struggle for life, the prevalence of greed and suffering, and most of all the universality of impermanence and decay. Accordingly, Asian Buddhists do not usually object to GM food as being “unnatural” – with one significant exception.

The press release of the Dharma Realm Buddhist Association (a Chinese organization) also asserts that lack of labeling “is a de facto violation of religious freedom” because it becomes difficult to avoid GM foods, a particular problem for Buddhist vegetarians who may want to avoid non-vegetarian genes in their vegetables. There is nothing in the five basic ethical precepts of Buddhism (to avoid harming living beings, stealing, lying, improper sex, and alcohol) that implies that a scientist should not take a gene from one species and transfer it to another one, especially if such genetic modification would improve the food. For most Buddhists, however, a genetically modified turkey so enlarged for breast meat that it could not walk clearly would be unacceptable, not because such a turkey is unnatural, but because such a chicken would suffer.

Some Chinese Buddhists, however, have expressed concern about transferring animal genes into plant foods. Transferring genes

between plants was less objectionable – as long as the genes of garlic, onions, scallions, shallots, and leeks were not used. The simplest explanation for the difference between these concerns brings us back to the point about cultural interaction emphasized at the beginning of this article: Theravadin Buddhists in South Asia follow the earliest teachings, which do not privilege “the natural.” Chinese Buddhism, in contrast, has been influenced by traditional Chinese values that emphasize harmony within society (Confucianism) and living naturally (Taoism).

Emphasis on Motivation

Buddhists often express concern about the *motivations* behind the introduction of genetic modifications into food, highlighting the importance of *cetana* “intentional action” in Buddhist teachings. This emphasis on motivation and intention points at what is distinctive about the Buddhist perspective, so the rest of this article will address that perspective and what it implies for genetically modified food. This involves expanding the evaluation criteria beyond the narrow issue of traditional dietary restrictions by considering broader issues about how consistent GM food is with Buddhism’s basic worldview and understanding of human motivation.

One of the ways that Buddhism explains *dukkha* “suffering” is by tracing it back to the “three poisons” (also known as the “three unwholesome roots,” *akusala-mula*) of human motivation: greed, ill will, and delusion (*Numerical Discourses*, Thera and Bodhi 1999). The Buddhist doctrine of karma can be understood in this fashion: when one’s actions are motivated by greed, ill will, or delusion, there are negative consequences that increase suffering. To reduce one’s *dukkha*, these need to be transformed into their positive counterparts: greed into generosity, ill will into friendliness, and the delusion of a separate self into the wisdom that acknowledges one’s nonduality with the world.

In order to consider the implications of this teaching for generic modification, it is necessary to highlight the Buddhist solution to delusion,

which means emphasizing the “three basic facts”: in addition to *dukkha*, these include *anicca* “impermanence” and *anatta* “nonself” (Thera and Bodhi 1999).

Anicca means that nothing is eternal, everything arising and passing away according to conditions, including ourselves. Socially, this implies an openness to change, including progress – if it really is progress, i.e., an improvement of previous conditions. That technologies are new is not a problem, for the important issue is their effects on our *dukkha*. Buddhists are not nostalgic for some prelapsarian age in the past when life was good because “natural” because there never was such a golden age.

The delusion that *anatta* resolves is duality: our usual sense of self as something separate from the external world that we are “in.” This is the most troublesome *dukkha* of all because the groundlessness of our constructed self is usually experienced as a sense of *lack* that we are unable to resolve: we feel the need to make ourselves more real, more substantial, but can never do so because the self is a psychological and social construct having no “substance” of its own that could become real.

In contrast, the wisdom of *anatta* is realizing that nothing has any substantiality or “self-being,” not only because there is no permanence but also because everything is interdependent on everything else, without any reality of its own. Nevertheless, that we do not need to worry about disturbing genetic “essences” does not liberate us to do whatever we want technologically. The most important criterion for Buddhism remains *dukkha*: does a genetic modification tend to reduce suffering, or increase it? Emphasis on interdependence complicates such an evaluation, and, unsurprisingly, this is where there have been the most problems, due to unexpected “side effects”: for example, Bt corn pollen alleged to kill monarch butterflies, allergic reactions due to the Cry9C protein in StarLink corn, cross-pollination of native Mexican maize, genes from genetically engineered plants found in the guts of honeybees, etc.

What do these Buddhist principles imply about GM food? The traditional Buddhist approach

focuses on how the three unwholesome roots of motivation – greed, ill will, and delusion – function on the individual level, but an important issue in contemporary Buddhism is whether they also operate collectively and institutionally. If so, does the law of karma still imply unwholesome results – not in some magical way, but in the sense that we reap what we sow? The issue is where the motivations behind the development and introduction of GM food fit into the karmic process, as understood by Buddhism.

For a brief period, “golden rice” genetically engineered to include beta-carotene (which our bodies convert into vitamin A) was proposed for nutritional deficiencies in some undeveloped countries, until it was realized that the amount of beta-carotene that could be added was too small to be significant. A more significant and notorious example of GM, however, was Monsanto’s attempt to introduce a patented “terminator gene” into the world’s main food crops. In general, genetic modifications seem designed to benefit the food industry more than the food consumer. The focus is on growing and processing food more efficiently and profitably, rather than on taste or nutrition. In a competitive industry, this may end up reducing consumer prices, yet it is not otherwise clear that GM in food has been contributing to the reduction of consumer *dukkha*.

On the other side, there is a noticeable and continuing pattern of unexpected problems, often for those who have not asked for GM food and may have little to gain from it. A few contested examples were cited earlier. Monarch butterflies feed exclusively on milkweed leaves, and in 1998 it was claimed that milkweed contamination from Bt corn pollen was killing them. Also in 1998, Arpad Pusztai, a scientist working in Britain, reported that in his experiments genetically modified potatoes were causing immune system damage to rats. In 2000 StarLink corn, with a protein indigestible to humans, was accidentally released into the human food chain, leading to 37 reports of serious allergic reactions investigated by the U.S. Food and Drug Administration. In 2001 Ignacio Chapela and David Quist, researchers from the University of

California, claimed to have discovered that genes from biotech corn had contaminated native maize in the Mexican highlands (Hart 2003).

There are at least two reasons to be concerned about such incidents, in addition to the specific problems they reveal. First, they support what the Buddhist emphasis on interdependence implies: that meddling with the genome of food plants and animals is an extraordinarily complicated process with many types of subtle consequences that are very difficult to anticipate and evaluate exhaustively. As a consequence, we can expect these types of accidents to recur indefinitely. Equally disturbing has been the reaction of the food industry, which has tried to deny or minimize these incidents, and – particularly in the cases of Pusztai, and Chapela and Quist – has undertaken questionable public relations campaigns to impugn their scientific competence and personal integrity.

What do these concerns reveal about institutional motivation? We are reminded that the food industry is a food *industry*. Providing nutritious and healthy food – something more complicated than producing most other consumer products – is not the ultimate goal in this system but the means within a larger economic process in which the focus is on productivity and profitability. Given the extraordinary difficulties with testing for possible adverse effects, along with corporate pressures for short-term profitability and growth, there are inevitable questions about whether the food industry can be trusted to place top priority on safeguarding the needs, not only of human consumers, but of the ecosystems that its modifications affect. Furthermore, given the strong corporate influence on governmental agencies – especially in the United States – there are also important questions about whether, for example, the Food and Drug Administration can be trusted to prioritize the needs of consumers and the biosphere.

In terms of the karmically significant motivations discussed earlier, the larger ethical problem here might be characterized, from a Buddhist perspective, as *institutionalized greed*.

Is there a correlative problem with *institutionalized delusion*? If there is a problematical duality between the institutional interests of food

producers and individual interests of consumers, there is a larger one between the human species and the rest of the biosphere. Since the advent of the modern era, our escalating technological powers have been used to exploit the rest of the biosphere, with little concern for the consequences of our domination for other species. We continue to act as if the other beings with which we share the earth have no value or meaning except insofar as they serve human purposes. The underside of our own evolutionary success is an ecological crisis that is already seriously affecting the quality of our own lives. The nonduality between ourselves and the rest of the biosphere – a collective version of the wisdom that Buddhism emphasizes – means that these two consequences are inseparable. There are no “side effects,” only consequences we like and consequences we do not like. Since we are part of the natural world, if we make nature sick, we become sick. From a Buddhist perspective, this is a paramount example of karma.

The genetic modification of food is only a part of this larger commodification process, but a significant part, since technological modification of other plant and animal species, without a much better understanding of their genomes and how all the genomes of living creatures affect each other, seems to be an especially dangerous example of how our ambitions can outrun our wisdom. From this perspective, the genetic engineering of food, as presently practiced, may be incompatible with basic Buddhist teachings, because it is inconsistent with the kinds of personal and collective transformation of motivations necessary if the basic problem of *dukkha* – not only human *dukkha* but that of other living beings as well – is to be addressed successfully.

This does not necessarily mean that the genetic modification of food is always something that should be avoided, which would be an “essentialist” claim inconsistent with the primary Buddhist emphasis on reducing *dukkha*. Since Buddhism does not privilege “the natural,” including the natural selection that drives the evolutionary process, there is the possibility that some genetic modifications might actually serve to reduce *dukkha*. Although it would need to be very

carefully tested, there is the possibility that a vitamin A-enriched rice might someday be a benefit to humankind without being a threat to the rest of the biosphere.

Summary

Historically, the most important issue regarding food has been whether or not Buddhist emphasis on compassion implies vegetarianism. Theravadin (South Asian) Buddhists generally eat meat and fish unless they know or suspect that it was killed purposely for them. Devout Mahayana Buddhists in East Asia are usually vegetarian.

Recently the issue of genetic modification has become controversial. From a Buddhist point of view, technologies are neither good nor bad in themselves. Nor are they neutral. That is because technologies cannot be separated from the larger social, economic, and ecological contexts within which they are devised and applied. The Buddhist understanding of karma as *cetana* implies that personal and institutional motivations are an essential part of that context. This means that any attempt at evaluating a technology such as the genetic modification of food needs to take the motivations behind those innovations into account.

Introduction

Citing public anxieties about the use of hormones in livestock production in the 1980s, the European Union (EU) banned the nontherapeutic use of a number of synthetic and naturally occurring hormones in domestic beef production and subsequently banned imports of beef produced using these productivity-enhancing hormones. The US and other beef-exporting nations such as Canada argued that the import ban was not justified on scientific grounds and was instead disguised

protectionism. Thus began a long-running and often acrimonious trade dispute between the EU and the USA along with Canada. The trade dispute highlights the challenges of dealing with consumer suspicions of a technology to all intents and purposes deemed “safe,” the conflict between a precautionary principle approach to technology versus a science-based risk assessment approach, and the challenges for the international trade architecture in distinguishing between policies motivated by nefarious protectionism and genuine consumer concerns. At the heart of the ethical dilemma posed by the US-EU beef hormone dispute is the reality that the World Trade Organization (WTO) was not set up to deal with consumers’ demands for protection (who are usually expected to benefit from trade liberalization) – its primary focus traditionally has been demands for protection from domestic producers. The beef hormone dispute proved to be a challenging first test of the WTO dispute settlement mechanism.

This essay outlines the origins of the US-EU beef hormone dispute and traces the turbulent history of the dispute through various WTO rulings, responses, and outcomes. The chief arguments put forth by the EU in defense of its beef import ban and by the USA and Canada in challenging the import ban are examined. The ethical issues raised by the trade dispute and potential solutions are explored with reference to key literature on the topic. The essay concludes by discussing the implications for trade policy of

the clash between a scientific rationality and a social rationality approach to new technologies.

Origins of the Beef Hormone Dispute

Growth-promoting hormones are commonly used internationally to enhance the production efficiency of livestock. The beef hormone trade dispute revolved around six hormones that were licensed for use in North America but banned in the European Union: estradiol-17 β (also called oestradiol-17), progesterone, testosterone, melengestrol acetate, trenbolone acetate, and zeranol. The first three are produced naturally in animals and humans, while the others are synthetic hormones (Kerr and Hobbs 2005). The three naturally occurring hormones are permitted for animal therapeutic purposes in the EU if used under veterinary supervision.

The EU hormone ban arose from growing public anxieties over the use of hormones in livestock production in the late 1970s and early 1980s (Roberts 1998). In the late 1970s, Italian schoolchildren began exhibiting signs of premature development which was believed to be linked to the use of illegal growth hormones in veal or poultry served in school lunches. A public furor ensued, with further investigations discovering residues of an illegal growth promotant in samples of veal-based baby food sold in Italy. These widely publicized “hormone scandals” prompted veal boycotts across a number of European countries and led to official proposals to ban the use of growth-promoting hormones in cattle production. The first European Commission Directive partially banning the use of growth hormones was passed in 1981, with a stronger ban on their use both domestically and in imported beef adopted in 1985 – subsequently annulled following a European Court of Justice challenge – and then readopted in 1988 (Roberts 1998).

Following the trade ban, exports of beef products from the USA and Canada to Europe fell precipitously, with US beef exports falling from 76,000 t in 1982 to just 4500 t by 1990 (Kastner and Pawsey 2002). The value of lost exports from the USA and Canada has been estimated at over

100 million dollars (Roberts 1998). The USA, Canada, and other beef-exporting nations objected to the ban on imports of beef, arguing that an overwhelming scientific consensus existed on the safety of beef produced using approved growth hormones. In addition to almost 50 years of scientific study, it was argued that the long-term use of hormones in beef production had been widespread in a number of countries for decades with no known food safety or health consequences. In the view of the USA and Canada, the absence of a scientific basis for the import ban pointed toward disguised protectionism as the true underlying motivation. Beef producers within the EU were placed at a significant competitive disadvantage vis-à-vis producers in the USA and Canada since they no longer had access to the productivity-enhancing hormones as an input to beef production. Furthermore, there were suspicions that the domestic ban on hormone use in the EU may also have been motivated by a desire to reduce the increasingly burdensome costs of the European Common Agricultural Policy (CAP) by lowering productivity and thus reducing aggregate beef supply (Roberts 1998).

For its part, the EU maintained that an appropriate level of protection was a societal value judgment and that it had the right to adopt a precautionary approach seeking a “zero risk” level if it so chose. It claimed that scientific questions still remained regarding the long-term effects of hormone use, as well as possible synergistic effects with hormones taken for medical purposes. Apparent widespread consumer opposition to the use of the technology also factored into the EU’s position, creating a political challenge for decision makers. The tendency for politicians to exercise “political precaution” when faced with public pressure to act even when the scientific evidence suggests little evidence of a problem has been recognized in other contexts (see Kerr 2009).

The WTO Dispute Settlement Mechanism

Protracted bilateral negotiations between the parties failed to resolve the dispute, and in the late 1980s,

the USA and the EU entered a period of retaliatory and counter-retaliatory trade measures. The existing mechanisms within the General Agreement on Tariffs and Trade (GATT) architecture proved unable to resolve this dispute. In 1995, however, the new World Trade Organization (WTO) came into existence, bringing with it strengthened trade rules around the use of trade restrictions for sanitary and phytosanitary reasons, as well as a new dispute settlement mechanism.

The WTO Sanitary and Phytosanitary (SPS) Agreement allows the imposition of trade barriers in instances where a country determines that imports may pose a threat to plant, animal, or human health. An SPS trade measure, however, must have a sound scientific rationale. In the cases of suspected SPS hazards, where a country claims there is insufficient information for a full risk assessment, the SPS Agreement explicitly states that precautionary trade measures should be temporary and any country invoking SPS measures should actively seek to fill in the gap in scientific information (Kerr and Hobbs 2005). The SPS Agreement defers to various international scientific bodies for a scientific consensus on acceptable levels of risk, including the Codex Alimentarius Commission in the case of food. In 1995 a Codex Committee voted narrowly in favor of standards governing the continued use of five of the six hormones (Kastner and Pawsey 2002). The USA and Canada argued that the EU beef hormone ban was in violation of the SPS Agreement given the lack of scientific evidence of a threat to health, and in 1996 both the USA and Canada applied for WTO dispute panels to adjudicate the EU hormone ban.

The WTO panel rulings followed in 1997, concurring with the USA and Canada that the EU ban on beef treated with growth-promoting hormones was inconsistent with its obligations under the SPS Agreement. The WTO Appellate Body was subsequently asked to review the dispute panels' decisions and in a subsequent ruling in January 1998 upheld the original WTO dispute panel rulings, finding that the EU had not produced scientific evidence to support the claim that the ban was justified (Roberts 1998). While the EU initially indicated that it would comply with the ruling, a

protracted period of negotiation ensued between the EU and the USA and Canada regarding the time frame for implementation, with the matter eventually being referred to a WTO arbitrator. Ultimately the period of time required for the EU to come into compliance expired in May 1999 at which point the EU indicated that it would not comply with the WTO ruling. This fraught first test of the newly established WTO dispute panel settlement mechanism threatened to undermine the credibility of the entire WTO dispute settlement architecture with repercussions that reverberated far beyond the economic significance of the loss in trade represented by the beef hormone dispute itself.

Refusal to comply with a dispute panel ruling, while expected to be rare, had nevertheless been allowed for by the framers of the WTO. A country that chooses not to comply can either offer compensation to the affected party (or parties) or accept retaliation against alternative products up to the value of the trade affected by the "illegal" trade measure. As Kerr and Hobbs (2005) indicate, countries rarely choose the compensation option because it is set to the gross value of the trade loss, while retaliation only results in a net value of trade loss since the goods retaliated against can find alternative markets. The EU opted for retaliation. Consequently the USA and Canada imposed 100% ad valorem tariffs on a range of agricultural commodities concentrated on politically influential countries in the EU: primarily against exports from France, Germany, Italy, and Denmark (the latter being a large livestock exporter). Kerr and Hobbs (2005) detail the initial retaliatory product list, while Johnson and Hanrahan (2010) chart the changes in these product lists over time. Among others the affected products included meat of bovine animals, meat of swine, Roquefort cheese, onions, cucumbers, tomatoes, truffles, mustard, soups, hams, chocolate, jams, yarn, oats, sausages, and certain juices.

Retaliation is widely regarded as counterproductive to the fundamental purpose of the WTO since it means putting in place additional trade barriers. Retaliation, while imposing costs on the EU, could do little to ease the economic burden on

the affected beef industries in the USA and Canada. The result is a loss in economic welfare: consumers in the USA and Canada pay higher prices for a range of food products, while producers in innocent industries in the EU suffer from the imposition of tariffs on their exports and lost market share. To further increase the pressure on the EU to review its position on the hormone ban, the USA threatened to employ a so-called carouseling strategy whereby the list of retaliatory products is frequently changed. Intermittently and randomly changing the imposition of retaliatory tariffs across different products is a more effective retaliatory strategy because it introduces greater levels of instability for exporters in the affected country and should increase internal political pressure to comply with the WTO ruling (see Kerr and Hobbs 2005, for a more detailed discussion of the carouseling strategy). For its part, the EU appeared to take the threat of carouseling seriously and has attempted to have the practice outlawed as a WTO retaliatory measure.

Over the following years, the trade dispute remained unresolved, with the EU maintaining its import ban on beef produced using growth hormones and the USA and Canada maintaining their retaliatory tariffs. The EU continued to commission research studies in an effort to garner scientific support for its hormone ban. In 2003, based on a risk assessment report suggesting that estradiol-17 β may be carcinogenic, the EU issued a new directive permanently banning estradiol-17 β and provisionally banning the other five hormones while further studies were undertaken. Claiming that this now placed it in compliance with its WTO obligations, in 2004, the EU requested WTO consultations to have the USA remove its retaliatory trade measures. In 2005 the EU initiated new WTO dispute settlement proceedings against the USA and Canada regarding their continued retaliatory trade sanctions. A March 2008 WTO panel ruling found all three parties to be at fault: the EU for still failing to present sufficient scientific evidence to justify the import ban and the USA and Canada for procedural violations in maintaining their trade sanctions. The WTO

Appellate Body subsequently heard appeals by all three parties to the earlier dispute panel ruling and in October 2008 issued a ruling allowing for continued trade sanctions against the EU but also allowing the EU to continue its ban on beef imports treated with growth hormones. This apparent mixed ruling did little to resolve the escalating dispute between the parties, and following US announcements in late 2008 and early 2009 signaling an increase in retaliatory tariffs on a wider range of products, the EU prepared to file a new WTO challenge against the USA and Canada regarding their use of retaliatory measures (Johnson and Hanrahan 2010).

Bilateral negotiations continued, and in May 2009, the USA and the EU signed a memorandum of understanding (MOU) outlining an agreement to resolve this 20-year trade dispute through a series of phased-in measures allowing expanded market access into the EU at zero duty for beef produced without growth-promoting hormones (so-called high-quality beef), balanced by a phased reduction in the removal of the US retaliatory import duties. Canada and the EU developed a similar MOU. The amounts of the US and Canadian (and third country) beef allowed into the EU by this resolution of the trade dispute are remarkably small: phased-in duty-free access for 48,200 t of non-hormone-treated beef (Council of the European Union 2012). In return the USA and Canada suspended their retaliatory import duties. Nevertheless, these agreements appear to have drawn to a close a protracted and bitter trade dispute that ranged over two decades and at times threatened the credibility of the entire WTO dispute settlement mechanism. The ultimate outcome appears to have been a reluctant acknowledgement by the USA and Canada that the EU was not going to lift its ban on hormone-treated beef regardless of the weight of scientific evidence to the contrary and that further retaliatory trade measures would only serve to escalate trade tensions at a time when closer trade ties were being contemplated (an EU-Canada Free Trade Agreement is currently under negotiation; an EU-US trade and investment pact is being contemplated) (Viju and Kerr 2011; ICTSD 2012).

Issues Raised by the Dispute

Embedded in the beef hormone dispute are a number of controversial, ethical, social, and policy dilemmas: a social rationality approach to policy decisions – including emphasis on consumers’ “right-to-know” and the use of the precautionary principle as a decision tool – versus a scientific rationality approach to policy decisions; challenges in distinguishing between genuine public concerns versus nefarious protectionism disguised as public interest; foregone benefits, the loss in economic welfare from trade barriers and retaliatory measures; and whether labeling of beef would have been a viable solution.

At its heart, the beef hormone dispute reflected a fundamentally different approach to policy decisions at the technology-safety interface in the EU relative to the USA and Canada. This difference is also manifest in other technology contexts, most notably the regulation of genetically modified foods. While risk analysis plays a central role in both policy processes, science is rarely definitive: one cannot “prove” that something is 100% safe. A *scientific rationality* underpins the US and Canadian approach to new technologies, while the EU has tended to adopt a *social rationality* stance (see Isaac 2002; Isaac and Hobbs 2002, for a detailed discussion of scientific versus social rationality in a policy context).

Underlying scientific rationality as the arbiter of policy decisions is a basic belief in technological progress, a consideration of both recognized and hypothetical risks, a focus primarily on safety and health considerations in risk assessments, an innocent-until-proven-guilty approach to the burden of proof, an acceptance of minimum risk tolerance levels, a strictly scientific interpretation of the precautionary principle, and the use of mandatory labeling confined to circumstances where hazards may exist (Isaac 2002). In contrast, technological precaution lies at the heart of a social rationality stance, with consideration not only of recognized and hypothetical risks but also of speculative risks, the burden of proof requirements resemble a guilty-until-proven-innocent approach, risk tolerance levels favor zero risk, there is a social interpretation of the precautionary principle, and

mandatory labeling is utilized more broadly based on consumers’ right-to-know (Isaac 2002). These divergent regulatory trajectories set the scene for different regulatory decisions on the approval of new technologies and processes (or the removal from the market of existing technologies and processes as new information emerges). Asymmetric and asynchronous approvals pose a significant challenge in international markets, ultimately leading to trade disputes.

The beef hormone dispute highlighted the challenges in dealing with trade barriers put in place due to apparent consumer concerns about a product or a technology. The challenges are twofold: first, distinguishing between genuine consumer concerns and nefarious protectionism, and second, even given genuine consumer anxiety, how should the trade policy architecture respond if the balance of scientific evidence suggests little to no risk? One might expect differences in quality perceptions across countries for cultural, historical, and social reasons (Bureau et al. 1998). A number of studies have examined European consumer preferences for beef produced with and without the use of growth-promoting hormones, as well as the extent to which these preferences differ across different countries (see, e.g., Lusk et al. 2003; Alfnes 2004; Tonsor et al. 2005). Using stated preference techniques, these studies find that consumers tend to discount hormone-treated beef and express a preference for hormone-free beef. The strength of preferences, however, varies among consumers and often across countries. For example, Lusk et al. (2003) found that French consumers were willing to pay relatively more for hormone-free beef than consumers in the UK, Germany, and the USA, and although consumers in the latter three countries did exhibit a positive willingness-to-pay (WTP) for hormone-free beef, there was no statistical difference between them. Within-country preferences also differed: heterogeneity in consumer attitudes toward hormone-treated vs. hormone-free beef was found to be stronger in the USA and the UK, while consumers in Germany and France tended to exhibit more homogenous preferences (Lusk et al. 2003). In a separate study, Tonsor et al. (2005) find that consumers from the UK, France, and Germany

exhibit distinctly different preferences toward hormone-free beef.

Hormone-treated beef is a credence attribute, meaning that its presence cannot be detected either before purchase or after consumption. In the absence of labeling, credence attributes create quality uncertainty in markets. Consumers who regard hormone-treated beef as lower quality, and who are unable to distinguish between hormone-treated and hormone-free beef, will reduce their demand for beef given quality uncertainty. The loss in welfare due to an adverse quality effect must be balanced against the potential gain in welfare from a technology that enhances productivity and lowers costs (a similar argument pertains to genetically modified food; see Gaisford et al. 2001, chapter 4). Bureau et al. (1998) show that trade liberalization in the presence of information asymmetry can be welfare reducing in the absence of labeling. To avoid these welfare losses, labeling is frequently proposed as a solution to information asymmetry. One of the potential solutions to the EU-US/Canada beef hormone dispute, therefore, would have been to allow production and importation of hormone-treated beef within the EU and to identify through labeling either hormone-free or hormone-treated beef.

While it sounds like a simple solution, in reality labeling raises some thorny policy questions. Should labeling be mandatory or voluntary? Should hormone-free beef be labeled or should labeling be used for hormone-treated beef? A voluntary hormone-free label should be welfare enhancing if the benefits (removal of quality uncertainty) outweigh the costs of implementing and enforcing the label. If the segregation and labeling costs are prohibitive, however, or if there is widespread cheating (mislabeling of hormone-treated beef as hormone free to capture a market premium), then a voluntary hormone-free label would fail to resolve the quality uncertainty in the market. On the other hand, requiring mandatory labeling of hormone-treated beef introduces further distortions into the market. Since consumers are heterogeneous in their attitudes toward the use of hormones in beef, not all consumers benefit from the additional information, and there are questions over the signal sent by

the label. Under WTO rules countries are permitted to introduce mandatory labeling requirements only if foreign products are treated no less favorably than domestic products (Roberts 1998). Labeling for health or safety reasons must have a scientific basis. If requiring the labeling of hormone-treated beef implied a health risk where none existed, then it may have done little to assist consumers in making informed choices and would have discriminated against beef imports from countries where use of productivity-enhancing hormones was standard practice. Whether some consumers have a “right-to-know” regardless of the potential economic costs to other groups in society remains a controversial issue and is apparent in other dilemmas such as animal welfare and genetically modified organisms.

Summary

The beef hormone dispute persisted for more than two decades and proved difficult to resolve despite the existence of the WTO SPS Agreement and the WTO dispute settlement mechanism. At its heart lay divergent approaches to agricultural technologies and the use and interpretation of science-based risk assessments as an arbiter of policy decisions. The balance of evidence suggested little scientific support for a ban on imports of hormone-treated beef on the basis of health risk. This finding was upheld through numerous WTO processes. Yet some European consumers express a clear preference for hormone-free beef. Retaliatory trade measures, meant to force compliance with WTO rulings, introduce further trade distortions in the long run. The ultimate significance of the beef hormone dispute stretches well beyond the economic losses from forgone beef trade and represents a potentially problematic precedent for the international trade policy environment.

Introduction

The First Nations are the largest of the three Indigenous groups (First Nations, Metis, and Inuit) of the Indigenous population living in Canada. First Nations people come from various nations such as Ojibwe, Cree, Ojicree, Salish, Mohawk, Dene, etc., depending on the region

Canadian First Nations and Food, Fig. 1 Framework for food security among Canadian First Nations people

in which they are from and are then further divided according to community/band across Canada. While many First Nations people live on-reserve, an increasing number live off-reserve; according to the 2011 Census, the off-reserve Indigenous population growth is surpassing any other demographic in Canada (Aboriginal Affairs and Northern Development Canada 2013). Recent estimates indicate the majority of First Nations are living off-reserve in urban areas. This encyclopedia entry will focus on First Nations people living both on- and off-reserve.

First Nations people procure food through two overlapping food systems: traditional foods and market foods (Fig. 1). Nutrition transitions among First Nations populations have been influenced by changes to both of these food systems, which in turn have impacted food security and nutritional status, in conjunction with socioeconomic disadvantage through colonialism. Importantly, these influences vary significantly by region (including living on-/off-reserve).

Traditional Food Supply

Traditional Indigenous foods can be defined as (1) originating from either local plant or animal

resources; (2) obtained through gathering, harvesting, hunting, trapping, or fishing; and (3) possess cultural meaning as a traditional food. Traditional foods and nutrient intakes vary depending on geography, seasonality, and cultural group. For example, coastal areas provide an abundance of seafood, northern regions offer caribou, and inland areas near freshwater offer fish. The introduction of modern agricultural practices by settlers also further influenced traditional food supply. For example, the use of wheat flour allowed First Nations people to make bannock. While many consider bannock to be a traditional food, there is controversy regarding this categorization because wheat flour was brought by Europeans. Naturally, there is an extensive list of traditional foods for Canadian First Nations that has not been fully documented, is continually fluctuating, and whose preparation is constantly evolving. For this reason, this encyclopedia entry will not discuss or list specific foods. Nevertheless, traditional foods are generally considered nutritionally superior compared to market foods available in stores today (Elliot and Jayatilaka 2011; Willows 2011). The nutritional benefits of these foods include being low in saturated fat and high in iron, zinc, vitamin A, and calcium. Importantly, traditional foods provide many significant holistic health

benefits, such as improving community health and strengthening cultural identity. For example, today many communities organize community hunts, sponsored by their band, to obtain traditional foods and share among their community.

Nutrition Transition

Colonization has and continues to play a critical role in the “nutrition transition” – the transition from an exclusive traditional diet, and associated procurement activities, to a diet of primarily market foods. Colonization has been implemented in the form of the reserve system, the pass system, the residential school system, and the Sixties Scoop, among other colonial processes.

Threats to traditional food procurement began with impacts on animal populations (i.e., migratory patterns, population size) due to settlers and forced relocations of Indigenous peoples onto reserves. In many cases, reserves are located on poor quality land with fewer natural resources, such as on flood plains or poor soil quality. Despite these early influences, it has been reported that many northern Canadian First Nation communities were self-sufficient (aside from flour and sugar) as late as the 1950s (Lyll 2003).

The pass system on “Indian Reserves” required First Nations people to get permission from Indian Agents, who were Canadian government officials, in order to leave the reserve. During this time, the Indian Agents would often deny permission and therefore people could not go hunting, fishing, or gathering. While this system is no longer in place, the disruption to passing on traditional knowledge is difficult to reclaim.

During the residential school system era, all Indigenous children were forcibly removed from their homes and placed in schools run by various churches, mandated by the Canadian government. Strict rules forbidding any cultural practices, such as speaking a First Nations language, were enforced. Within the schools, many children experienced emotional, physical, and sexual abuse. These events have affected future generations through intergenerational trauma. This has had both direct and indirect effects on First Nations

people’s ability to procure traditional foods during that time as well as to this day.

The Sixties Scoop was another period in which First Nations children were forcibly removed from their homes. Parents were deemed “unfit” to parent and these children were adopted into Caucasian families or foster homes. Many adopted children did not grow up learning their culture and history, and this has resulted in the loss of traditional food ways.

Today, obtaining traditional foods through hunting or fishing is threatened by a number of factors, many influenced by the above events, such as the high associated costs; the loss of traditional knowledge in the family (not having a skilled hunter/fisher in the family); decreased acceptability of traditional foods by First Nations people (especially youth); increasing loss of traditional land; weakened cultural identity; increased urbanization, lifestyle adaptations, government restrictions, and regulations on hunting and fishing; as well as contamination and species decline due to pollution and climate change (Elliot and Jayatilaka 2011; Howard and Edge 2013; Willows 2011). Due to many of these constraints, First Nations people must often travel further to hunting grounds/fishing areas, necessitating additional special equipment (boats, snowmobile, etc.). These rising costs combined with low socioeconomic status have forced many to abandon hunting and fishing as ways of food procurement.

Environmental changes due to climate change, pollution, and contamination have varying influences on First Nations depending on region. Issues related to climate change have impacted animal populations to a greater extent in the north, whereas, pollution has impacted animal health in both southern and northern communities. For example, polychlorinated biphenyls (PCBs) have been documented in fish near First Nations land and have been implicated in the diabetes epidemic in these populations (Philbert et al. 2009). Similarly, First Nations people living in rural areas near farms are concerned over pesticides in hunting areas where herbivores, such as deer, eat. Flooding, particularly in the Prairie Provinces, has also impacted fishing season for many communities. Together, these environmental

factors influence the quality and quantity of the traditional food supply as well as people's willingness to continue consuming these foods.

Urban First Nations people are likely most affected by the "nutrition transition" as urban areas are most removed from access to traditional foods. Despite complex regulations regarding the buying and selling of traditional foods, there are stores in some urban centers that provide wild meats and wild fish (Cidro and Sinclair 2014); however, these products often have high costs and are of lesser quality (i.e., frozen). Additionally, First Nations people in urban areas are more likely to live in economically disadvantaged neighborhoods with greater access to non-nutritious western foods through fast food outlets, restaurants, and a higher concentration of convenience stores.

Procurement of Market Foods

Market foods are accessed in most settings that sell or serve food. First Nations people access these foods at grocery stores, restaurants, and community-based organizations. As part of the nutrition transition, most First Nation communities have road access to market foods, regardless of whether they are rural or remote.

Remote. A remote community (also known as fly-in remote) is defined as not having all-weather road access to a major urban center. Despite availability of market foods, there are significant costs associated with transportation to remote locations, particularly for fresh foods. For some communities there may be road access during the winter when lakes are frozen and freight costs are then decreased as compared to air freight. However, freight cost over winter roads is still higher compared to all-weather roads due to increased wear and tear on trucks, weight requirements, and weather issues. Other associated costs contributing to food costs in remote communities include the small market size of communities, travel for maintenance and repair, and higher utility costs, among others. For this reason, market food costs have long been extremely high in remote northern First Nations communities (Lyall 2003). For example, in

Saskatchewan, a family of four in a northern community can expect to pay over \$100 more per week compared to a southern community (Abrametz et al. 2012). Importantly, stores in remote communities often have limited stock and fewer food options compared to urban stores, particularly for fresh fruits, vegetables, and meats, which further compounds food security issues.

Rural. A rural community is defined as a community that has all-weather road access to a major urban center. While there is substantial research regarding descriptions of food insecurity with regard to food procurement in northern First Nations and Inuit communities, especially in reference to the price of store-bought foods, there is relatively little research regarding these important topic areas in southern communities. It is assumed that due to proximity to urban areas and lower prices of food in rural communities, that food environment and its relationship with food insecurity plays a lesser role in the development of health conditions compared to northern communities. In this regard, Gates and colleagues (2012) reported significantly lower milk and alternatives intake among students in more southerly, less remote communities compared to northern First Nation communities, in contrast to their hypothesis. However, there are few other studies describing food procurement among southern First Nation communities. On the one hand, the prices may be lower at grocery stores in rural communities, and on the other hand, **transportation** to larger urban centers, hence grocery stores, is a major barrier. In this way, many First Nation people in rural communities are limited to convenience stores and smaller grocery stores with improved proximity to their community.

Urban. For First Nations people in urban settings, procurement of market foods is widely available at many local grocery stores. However, due to socioeconomic disadvantage, many First Nations people live in under-resourced neighborhoods or urban food deserts (Cidro and Sinclair 2014); this forces people to find transportation to a grocery store. With limited financial resources, individuals may not have vehicles to drive to the grocery stores whenever they need food. Individuals are often left with two options: pay for a

taxicab or take the bus. Each option has its barriers, taxicabs are expensive and a limited number of groceries can be carried on a bus trip. People then will either buy foods from convenience stores or restaurants nearby for food in between larger trips.

Food Security

A major problem the First Nations population faces as a result of sociocultural, economic, political, and environmental barriers is food security. Food security is defined, according to the World Health Organization (1996), as existing when “all people at all times have access to sufficient, safe, nutritious food to maintain a healthy and active life.” For First Nations people, this includes security for both traditional and market foods and is impacted by many factors, beyond what is illustrated here (Fig. 1).

Extent of the problem. Canadian national surveys have shown that the burden of food insecurity is dramatically greater among the Aboriginal population than on the non-Aboriginal population. Twenty-seven percent of Aboriginal households in Canada are food-insecure; this rate is more than three times higher than the non-Aboriginal population rate (Willows et al. 2008). Importantly, Aboriginal status is significantly associated with food insecurity independent of other socioeconomic factors. While food security is known to be an issue among Aboriginal populations off-reserve, as just described, there is considerably less known regarding food security on-reserve because this population is excluded from national surveys. Although national surveys are informative for identifying risk factors for food insecurity, because the sampling frame excludes First Nations on-reserve, the burden of food insecurity has not been appropriately evaluated. First Nation-led Regional Health Surveys on-reserve, including questions relating to food security, will be the first to systematically look at food security across Canada. However, issues regarding appropriate measurement of food security on-reserve exist.

Measures of food security. Standard measures of food security have not been validated in an

on-reserve First Nations population and are not generally considered appropriate. Standard measures of food security focus exclusively on economic ability to purchase (i.e., access) food, which does not take into account the important component of traditional food. Finally, food sharing is common in First Nation communities, which contributes to as well as mitigates food insecurity and is not captured on standard food security questionnaires. There may be additional considerations that have not been explored and must be factored into appropriate food security measures. Additional research is needed.

Nutrition Status

The declining consumption of traditional foods coupled with increasing intake of market foods over time has contributed to a significant decline in First Nations’ nutrition and health status that is exacerbated by many factors such as poverty and food insecurity. As part of this shift, First Nations populations have been observed to have poor nutrient status, including undernutrition with respect to vitamin D, folic acid, calcium, fiber, and overnutrition with respect to fat and sugar (Delormier and Kuhnlein 1999). As a result, First Nations populations suffer from a disproportionate burden of diabetes and chronic disease compared to their non-FN counterparts (Tjepkema et al. 2012). However, an important feature of the diabetes epidemic is the heterogeneity of burden among FNs geographically, which closely reflects regional differences in economic disadvantage. Rural/remote environments, nutrition transitions, nutritional status of the population, food environment, and food security have been implicated as intermediaries between socioeconomic factors and health outcomes among First Nations populations.

Addressing Food Security

Food security is an important social justice issue among First Nation populations. Not only is the right to food a human right but it is also significantly related to adverse health outcomes. In a

developed and wealthy nation such as Canada, issues of food insecurity and access to clean drinking water are more strongly related to issues of political will rather than resources. Furthermore, many initiatives, both government and charitable, address only acute hunger through food banks and school programs, for example, but do little to address root causes of food insecurity.

Ideally, First Nations people are interested in working toward food sovereignty and regaining greater control over their own food systems. According to Food Secure Canada, food sovereignty is defined as, “the right of peoples to healthy and culturally appropriate food produced through ecologically sound and sustainable methods, and their right to define their own food and agriculture systems” (Food Secure Canada). The seven pillars include focusing on food for people, building capacity in food knowledge and skills, working with the land/nature, valuing food providers, localizing food systems by minimizing distance between providers and consumers, emphasizing local control, and respecting food as sacred (Food Secure Canada). In this way, food sovereignty includes a political dimension not captured by “food security” (Martens 2015).

As cultural foods were taken away with assimilation of First Nations people, it is imperative that interventions, policies, and programs do not create an “assimilated” approach and present another culture’s normative eating patterns as innately superior. This is important because many programs and interventions today are deceptively continued colonial discourse which is causing further despair for First Nations peoples in Canada. In this regard, there are many excellent initiatives in Canada to improve Indigenous food sovereignty that have been summarized by Martens (2015). These initiatives are varied and include community gardens, greenhouses, forest management training, traditional food education, research, and advocacy.

Conclusions

Canadian First Nations people are in varying levels of transitions between traditional foods to market foods

as an increasingly primary source of nutrition. This transition has occurred over time and has been influenced by many social, political, economic, and environmental factors that in turn influence the availability, accessibility, and utilization of both traditional and market foods among both on-reserve and urban First Nations people. Food security occurs at the interface of traditional and market food systems. In response to nutrition transitions among First Nations populations, communities are increasing control over their food systems and reclaiming traditional food. The move toward food sovereignty will likely contribute to greater autonomy and ultimately improvements in food security, nutrition status, and health.

Cannibalism

J. Jeremy Wisnewski
Hartwick College, Oneonta, NY, USA

Synonyms

[Anthropophagy](#); [Eating humans](#)

Introduction

Cannibalism, or anthropophagy, is the consumption of the flesh of one human by another. The word “cannibalism” itself comes from the Spanish “Canibales” – a name for the Carib tribe in the West Indies thought to engage in ritualistic cannibalism. The term “cannibalism” can also be used more broadly to mean the consumption of members of one’s own species. The Greek-based term “anthropophagy” quite literally means “eating humans,” regardless of who (or what) is doing the eating. Historically, a great variety of arguments have been offered against cannibalism, and virtually none in its favor. Nevertheless, reflection on cannibalism raises many very difficult conceptual issues, and few arguments against it are without serious problems.

To assess the arguments against cannibalism, three kinds of cannibalism will be distinguished. The relevance of the natural law tradition to cannibalistic activity will then be discussed. Following this, the relationship between respect for human beings and cannibalism will be explored, as well as the relevance of disgust to morally assessing acts of cannibalism. Finally, cannibalism will be assessed from the point of view of three traditional moral theories (rights-based deontology, utilitarianism, and virtue ethics).

Varieties of Cannibalism

In assessing the morality of cannibalism, three different kinds of cannibalism should be distinguished.

First, cannibalism is sometimes used as part of religious or cultural rituals. The cultural practice of anthropophagy can be called ritualistic cannibalism (or “learned cannibalism”). There have been many reports of groups of people around the world engaging in such ritualistic practice. The aims of such cannibalism vary. Rituals may involve the consumption of one’s ancestors as a way of showing respect to them, or it may involve other motivations: the desire for revenge, to crush one’s enemy, to eliminate internal or external threats, to magically stave off negative forces, or simply to feast. The indigenous population of

Easter Island and Papua New Guinea, to cite two familiar examples, is known to have engaged in various kinds of ritualistic cannibalism. The extent of anthropophagic ritual and practice today is not certain, but the practice undoubtedly continues in some parts of the world.

Cannibalism, when used to prevent starvation and not as a part of a cultural practice, can be called emergency cannibalism (or survival cannibalism). The famous Donner Party of 1846 as well as the Uruguayan rugby team that crashed in the Andes Mountains in Chili in 1972 both engaged in this form of cannibalism. There are also countless accounts of emergency cannibalism as a result of shipwreck. The aim of emergency anthropophagy is, by definition, survival.

A third kind of cannibalism can be called fetish cannibalism. This form of cannibalism is “fetishistic” because it is related to a fetish, often though not always sexual in nature, on the part of the person who engages in cannibalism. In such cases, cannibalism is practiced as a means of fulfilling the desire to consume human flesh. Jeffrey Dahmer is perhaps the most famous case of such cannibalism. Armin Meiwes, who was tried and convicted in German courts in 2002, likewise participated in fetish cannibalism when he killed and consumed Bernd-Jurgen Brandes, who had answered an advertisement Meiwes posted on the Internet seeking a volunteer who wanted to be killed and eaten.

Arguments from Natural Law

Discussions of natural law in the modern era (1600–1800) made frequent use of the figure of the cannibal. Discussion of cannibalism itself was widespread in the nineteenth century, largely due to the stories of travelers who had visited places where cannibalism was alleged to occur (Avramescu 2009). Herman Melville’s *Moby Dick* provides one literary example of the much discussed figure of the cannibal. Interestingly, however, Melville presents the cannibal (the character Queequeg) as both honorable and worthy of our respect – *not* as a moral monster. In a similar vein, in what is perhaps the most famous essay on

cannibalism, Michel de Montaigne (1993) acknowledges the immorality of cannibalism, but also insists that the practices of European nations (involving, e.g., torture) are far worse. While cannibalism may well be barbarous, Montaigne argues, it is no more barbarous than the actions of the so-called “civilized” world. Indeed, Montaigne suggests that it is *less* barbarous.

Many historical reports of cannibalism are now widely regarded as unreliable. Allegations of cannibalism in centuries past were sometimes made to justify the oppression of indigenous peoples or to secure funding to “civilize the savages.” It is difficult to know the exact extent to which allegations of cannibalism among indigenous peoples reflected such motivations. Certainly, though, the amount of cannibalism alleged to exist in the world was highly exaggerated throughout the nineteenth century and into the twentieth.

The central argument used against cannibalism in all its forms in the modern period relied on the concept of natural law. According to natural law theory, certain kinds of practices violate the order of the world – an order that is variously conceived as coming from some higher being (God) or as stemming from things like human nature. According to some of the standard arguments, the consumption of members of one’s own species among human beings violates this natural order and is therefore immoral. In the modern period, the relationship between cannibalism and natural law is discussed by thinkers as diverse as Hugo Grotius (2009), Samuel Pufendorf (1991), John Locke (1997), Michel de Montaigne (1993), and Thomas Malthus (1999), to name only a few.

Arguments from natural law, however, face significant objections. First, it is very difficult to determine (1) whether or not anything like “natural law” actually exists and (2) what the content of this law actually is. Indeed, cannibalism has sometimes been taken to be evidence against the existence of natural law (Avramescu 2009). Moreover, appeals to natural law frequently articulate one’s point of view rather than providing a justification for it. This can be seen when one’s only reason for saying that something is wrong is that the thing is “unnatural.” Leaving aside how we are to know what things are and are not natural

(a thorny issue), it is often contended that claims about what ought to be the case do not follow from facts about what is the case. This is typically called the “is/ought” problem and can be traced back to David Hume. One cannot claim that there shouldn’t be cannibalism (an “ought” claim) based on the claim that cannibalism is unnatural (an “is” claim).

One can even argue, however, that cannibalism *is not* unnatural. On one view, anything that natural biological organisms do is itself natural. If this is correct, then cannibalism is as natural as many other cultural practices – marriage, funeral rites, festivals, and so on. Some anthropologists have even argued that cannibalism was common among our evolutionary ancestors.

Thus, the appeal to “unnaturalness” faces two central objections: (1) something may well be morally permissible even if unnatural (this is an implication of the “is/ought” distinction), and (2) cannibalism may not be unnatural.

Appeals to natural law sometimes involve appeals, not to the natural order, but to the will of God. If cannibalism violates the will of God, one standard argument goes, it violates natural law. The difficulties with this view are fairly straightforward: (1) it is impossible to prove that any particular act either is or is not the will of God (there are many possible religious traditions to appeal to, and no definitive argument that one is superior to another), and (2) it is possible, in response to this line of argument, to simply deny the existence of God.

Respect and Cannibalism

Despite arguments against cannibalism based on the doctrine of natural law within religious traditions, many of these very same religious traditions involve at least symbolic cannibalism. The Eucharist, for example, involves the consumption of (a symbol of) the flesh and blood of Christ. One is eating the flesh of another (partial) human, at least symbolically, in communion.

The roots of this practice are shared by more obviously cannibalistic traditions. Cannibalism involves literally incorporating the human being

who is eaten. This is sometimes described as a means by which one pays respect to the deceased, allowing him to live on (symbolically) within the bodies of those who survive him. In this respect, ritualized cannibalism has sometimes been a means by which one honors the dead rather than a means by which to denigrate or disrespect the dead. Similarly, the Eucharist involves the internalization of Christ’s flesh as a means to symbolically make Christ a part of oneself.

In the case of ritualistic cannibalism, then, it is simply not clear that there is anything intrinsically disrespectful in *all* anthropophagic cultural activities. If some forms of ritualistic cannibalism are not inherently disrespectful, it follows that cannibalism itself is not inherently disrespectful (i.e., there is at least one kind of cannibalism that is consistent with maintaining respect for the cannibalized).

In the case of emergency cannibalism, it can be argued that no disrespect is intended (though this does not guarantee that disrespect is not present). In emergency cannibalism, after all, one only consumes human flesh to avoid starvation. Nevertheless, one can certainly imagine some cases of emergency cannibalism that involve disrespecting those eaten. This indicates that the circumstances of the cannibalism will be the determining factor in deciding whether or not respect for persons has been violated.

In the case of fetish cannibalism, disrespecting the person cannibalized is much more common. In most cases of this kind of anthropophagy, a person is murdered and then eaten. All cases of murder (though not necessarily all cases of killing) involve disrespecting the person murdered (one doesn’t acknowledge the person’s desire and right to live). Nevertheless, there is at least one case in which fetishistic cannibalism was contingent on the consent of the cannibalized. In the 2002 case of Armin Meiwes, Meiwes actually released one potential victim of cannibalization when the voluntary victim revoked consent (Wisniewski 2007). He also went to great lengths to document the consent of Bernd-Jurgen Brandes, utilizing video-taping as well as written consent prior to actually killing and eating him. If respect for persons involves requiring their consent to whatever one intends to do to them (an arguable, but

nevertheless plausible, account of what respect involves), then fetish cannibalism is at least in principle consistent with respect for persons (even if in practice it is usually not).

Consent and Cannibalism

Some argue that consent to cannibalism mitigates any wrongdoing involved in it. Provided it is possible to consent to cannibalism, then, consent transforms an otherwise immoral act into a permissible one. One response to this argument is to claim that consent cannot be given, as only someone who is irrational would agree to be eaten. This reply, however, is circular. Fetishes are by definition irrational. It does not follow from this that one cannot consent to participate in a fetish. If one insists all cases of fetish cannibalism are illegitimate, one has simply presupposed that it is impossible to consent to cannibalism. Of course, this is the very question which is at issue in moral debates about anthropophagy (is cannibalism ever permissible?). If one begins with the assumption that cannibalism cannot be the object of consent, one cannot then claim that this assumption proves the impermissibility of cannibalism. More argument is needed (Wisnewski 2004, 2007).

Another objection that can be raised against the view that consensual cannibalism is acceptable goes as follows: any moral doctrine which concludes that cannibalism is moral must be mistaken. If an emphasis on consent has this implication, then there must be something wrong with the doctrine that consent can transform an immoral action into a moral one. If consenting can justify cannibalism, the objection runs, then it can justify *anything*. This by itself might be taken to indicate that consent cannot be the only measure of the moral permissibility of an action. Of course, this line of objection also takes for granted the immorality of cannibalism rather than establishing it.

Arguments from Disgust

The most common immediate reaction to cannibalism is to claim that the practice is disgusting.

The moral relevance of an appeal to disgust, however, is hotly contested. While some philosophers argue that disgust *can be* morally relevant, few argue that it is always so. This means that any appeal to disgust must also rely on additional arguments if it is to make the case that disgust *in regard to cannibalism* demonstrates the immorality of that practice. Given that picking one's nose is disgusting, after all, hardly entails that it is immoral. Even if we all accept that eating another human being is disgusting, then, we have not yet shown that it is also immoral, let alone that it is immoral *because* it is disgusting.

Rights-Based Arguments

One argument against cannibalism states simply that cannibalism violates a duty we owe to other persons. This is sometimes captured by an appeal to the rights of other human beings. Specifying which right is violated by cannibalism, however, is a difficult task. If one claims that we have a right not to be eaten, one has simply asserted the conclusion in advance of providing evidence for it. To say that humans have a right to not be eaten is equivalent to saying that cannibalism is wrong (one cannot *conclude* that cannibalism is wrong simply by asserting it in alternative language).

To make a case against cannibalism based on human rights, then, one must appeal to a right that is not equivalent to the right not to be cannibalized and then show that cannibalism violates this right. There are several difficulties that must be overcome to make such a case.

Murder is not cannibalism. One might accept the claim that all persons have a right to life and thus conclude that any killing for the purpose of cannibalism violates this right to life while also maintaining that cannibalism itself does not violate this right. In other words, to kill in order to cannibalize is indeed a violation of the right to life; to cannibalize one who is already dead, however, does not violate this right.

One theoretical difficulty with the appeal to rights goes as follows: some have argued that only *living subjects* can have rights. On this view, the dead possess no rights, as the dead,

strictly speaking, *do not exist*. On this view, traceable to Epicurus and Lucretius, death is simply nonexistence. One must exist to have rights. Therefore, the dead cannot be said to have rights.

There are two plausible responses to this line of argument. First, one can argue that the dead do, in fact, have rights (or, put alternatively, that the dead can still make demands on the living). Second, one can argue that the living have rights that *involve* the dead, even if the dead themselves do not have rights.

The claim that the dead have rights is widely enshrined in western law. We protect the wishes of the deceased by carrying out their wills; we utilize laws to govern the exhumation of human remains, presumably because we collectively regard the dead as having a right to “rest in peace.” Of course, the fact that such rights are enshrined in law does not entail that they are justified. Nevertheless, such laws provide some evidence for the view that many *regard* the deceased as entitled to certain kinds of respect.

The claim that persons have obligations *regarding* the dead, even if the dead have no rights, is sometimes discussed in terms of indirect duties. Because a person has property rights, for example, I have a duty to that person to refrain from destroying his or her property. In this way, I have an indirect duty *to the property* because I have a direct duty to the person who owns this property. Analogously, one might think I have indirect duties to the dead because I have direct duties to the living. Thus, desecrating or disrespecting corpses, on this view, would amount to violating a duty I have to living human beings – perhaps the family of the deceased, who do not want their deceased loved ones interfered with, or perhaps even to society at large.

The question still remains, however, as to which right in particular is violated by cases of cannibalism. An appeal to the right to be treated with respect fails for reasons discussed above (see Respect and Cannibalism). After all, there are cases in which respect is shown *by cannibalizing a person*. Nevertheless, one might acknowledge that the means through which one shows respect differ across different cultures. On this view, then, showing respect will be an absolute obligation

(there is a universal right to it), even though the *means by which* one shows respect will differ across cultures. The conclusion here must be substantially weaker – namely, that it is wrong to cannibalize only in those cases where cannibalism represents disrespect for the dead. This conclusion, of course, is compatible with the claim that cannibalism is not universally wrong.

One might similarly argue that cannibalism violates a central principle of deontology, the ethics of duty. In one of its most famous formulations, duty requires that we treat human beings “as ends and never merely as means” (Kant 1999). To eat another human being, on this view, involves treating that person as a means (food) to a particular end (nourishment) and hence cannot be defended.

Two substantial problems can be raised against this deontological argument, however. First, one might argue that the right to be treated as an end (and not a mere means) does not extend beyond the grave. That is, one might argue that we only have a duty to respect the *living*. If this is correct, the above argument fails in the case of cannibalism, despite the fact that the duty holds among the living. More persuasively, one can point to ritualistic cannibalism as an example of respecting the dead (at least in those cases where it is used for this purpose). This seems to indicate that respect for persons, alive or dead, is compatible with at least some kinds of cannibalism and hence that cannibalism does not necessarily involve the absence of respectful treatment.

An appeal to universal rights not to be cannibalized has some unexpected consequences. In a strict case of emergency cannibalism, for example, an absolute and universal right against cannibalism entails that starving to death is morally required. Many people find this result counterintuitive. An emergency situation, by its very nature, is exceptional. Moreover, one might argue that certain otherwise immoral actions are permitted when these actions are necessary for life preservation. These concessions entail, however, that the prohibition against cannibalism cannot be absolute. Once we grant that there are some conditions under which cannibalism is acceptable, we grant that the range of permissible cases may be wider than we initially suspected.

Utilitarian Arguments

Utilitarianism is the view that actions are right or wrong in virtue of the consequences they produce, where we measure the consequences of an action in terms of some predefined good (pleasure, happiness, interests, preferences, etc.; see Mill 2002). Utilitarian arguments can also be given against cannibalism. Before considering these arguments, one should distinguish between those arguments that aim to show it would be immoral to legalize cannibalism (a policy question) and those arguments for the view that any individual act of cannibalism is immoral. Utilitarian consideration can arguably establish the first claim; they fall substantially short of the second.

On the policy side of the issue, one might argue that allowing (or encouraging) cannibalism will shape the way individuals within a society understand their fellow human beings. If we come to see one another as a source of food, this argument goes, we will have a fundamentally diminished view of other persons, and the consequences of this will be both far-reaching and dire. Because a healthy society must cultivate and maintain mutual respect among its citizens, accepting cannibalism when it occurs violates utilitarian principles. Ultimately, accepting cannibalism will diminish the well-being of every member of the society that practices it. Further, one might argue that a society in which the dead are not permitted to “rest in peace” would create anxiety *among the living* regarding what may befall their mortal remains. An increase in this anxiety, it might be argued, would thus produce more pain than pleasure (and hence should be rejected on utilitarian grounds).

Of course, the utilitarian must consider both short-term and long-term consequences. Given that there have been cannibalistic societies where the above argument does not seem to hold, one can respond to the above argument by pointing out that there is no necessary connection between anthropophagy and viewing persons as having diminished worth. After a few generations, the shock of cannibalism may no longer cause the kind of adverse reactions we currently associate with it. Nevertheless, this hardly entails that we have any reason whatsoever to pursue cannibalism at the level of social policy. As a policy

question, then, utilitarian considerations seem to indicate that nothing speaks in favor of allowing cannibalistic practices.

The same arguments cannot be made, however, when applied to individual cases. In fact, utilitarian considerations would seem to justify cannibalism in emergency situations. In such a case, the initial revulsion one faces is outweighed by the desire to avoid death and starvation. Moreover, even if we maintain that the dead person cannibalized has a postmortem interest in not being eaten, this interest would seem to be outweighed by the need to save lives. (This argument in favor of emergency cannibalism presumes that the person cannibalized is already dead. The view that we should kill someone in order to eat them, even in emergency situations, is a much more controversial matter.)

Evolution and Cannibalism

A roughly utilitarian argument is sometimes made from the point of view of evolution. If humans eat one another, the argument goes, the species as a whole will not benefit. There is some evidence that human consumption of human flesh increases the likelihood of Creutzfeldt-Jakob syndrome, a disease which attacks the central nervous system and which results from a buildup of prion proteins. Prions are spontaneously generated in humans even absent any cannibalism, though the consumption of human flesh containing prions increases the likelihood that one will acquire the disease.

Virtue Ethics and Cannibalism

A virtue ethics aims to identify and cultivate particular virtues within individual human beings. Virtues are dispositions, or states of character, that are conducive to human excellence and flourishing (Aristotle 1980). To argue against the consumption of human beings from within a tradition of virtue ethics, one would need to show that those traits that lead to anthropophagy are themselves not consistent with, or at least not conducive to, the virtuous life. However, simply asserting that cannibalism is not virtuous is not an argument, as it presupposes the very thing it

attempts to establish. To prevent arguing circularly, one must establish some specific trait or virtue that is violated by the practice. For example, one might argue that engaging in cannibalism makes it easier to view a person as a thing and that viewing persons in such a way is not part of the virtuous life. Such arguments, however, face the same obstacles we find in other cases: there have been societies that routinely engaged in ritualistic cannibalism, and some forms of ritualistic cannibalism do not seem to involve treating the cannibalized as a mere thing. Indeed, in at least some ritualistic cannibalism, the body of the cannibalized is regarded with a kind of reverence. While it is certainly possible that these cultures were engaging in practices incompatible with virtue, more argument is required to establish this. To insist that these cultural practices are illegitimate without providing such an argument may well be ethnocentric.

Summary

There are arguments against eating humans from virtually every major ethical tradition as well as from the majority of religious traditions. These arguments, however, rarely (if ever) cover every kind of cannibalism, and all face serious objections. The absence of arguments establishing a universal prohibition of cannibalism is not equivalent to the claim that cannibalism is morally permissible. It may be permissible in certain cases, but such cases will have to be assessed individually.

Carbon Farming

Gavin Harper
Cardiff University, Cardiff, UK

Carbon farming is a term used to describe agricultural activity that is undertaken with an express desire to improve the levels of carbon in the

atmosphere. Some approaches to carbon farming focus on reducing the output of carbon from agricultural activities. The term is also used to refer to agricultural activities conducted with the express intention of capturing carbon dioxide from the atmosphere in order to mitigate against climate change. Carbon is captured in the cells of living plants. At this stage, it can either be turned into another manufactured product, such as biofuel or biomass. This can be used by other processes or, in the case of charcoal, can be “sequestered” and plowed into the ground locking up the captured carbon. A range of land management, agricultural, and agroforestry techniques can be deployed with the intention of managing carbon.

The Carbon Cycle in Agriculture

Within the carbon cycle, there are a great many transactions taking place that exchange carbon between natural pools. As plants grow, they take carbon dioxide from the atmosphere and fix the carbon creating organic (carbon containing) cell matter. Thus, carbon is extracted from the atmosphere to the biosphere. Some of this carbon may find its way back into the atmosphere. If fuel from plants, wood, biofuel, or biomass is burned, the captured carbon in the cells of the plants will be released into the atmosphere as carbon dioxide. When animals or humans eat carbon containing plant matter and digest the food, it provides energy – the humans and animals producing carbon dioxide through the process of respiration. Furthermore, excreted products may return to the pedosphere – the soil. There are other ways that plant matter can return to the pedosphere. Biomass that is not utilized as a product may die back and return to the soil. One approach to carbon farming is that a crop is grown specifically with the intention of returning the carbon it absorbs through growth, into the pedosphere – sinking carbon from the atmosphere.

It is also important to consider that modern industrialized agriculture be also reliant on external inputs; some of which are carbon intensive. Agricultural equipment is often fossil fuel-powered transportation and logistics of

agricultural goods also generate carbon. In the United States, agriculture is responsible for 7% of total US greenhouse gas emissions. Furthermore, the variety of chemicals and pesticides used in some agricultural practices all require energy and hence carbon to manufacture. When assessing the carbon impact of agricultural activities, these external inputs need to be factored into the carbon accounting.

It is helpful to consider the relative proportions of carbon in the biosphere (575 Gt), the atmosphere (780 Gt), and the pedosphere (2700 Gt). Agricultural practices can modify the content of carbon in the pedosphere – either liberating it or sequestering additional carbon. As such, agriculture has an important role to play in managing global carbon levels.

Other Greenhouse Gases

In addition to carbon, agricultural processes also result in the release of significant quantities of other greenhouse gases which contribute to climate change. When accounting for the activity of different greenhouse gases, a measure is used known as “carbon equivalence.” This accounts for the fact that some gases have a much greater global warming potential than carbon dioxide. This is a measure of the effect these gases have on “radiative forcing” over a given time period, usually considered as 100 years. Of significance is nitrogen oxide and methane. Methane is 25 times more active as a greenhouse gas than nitrous oxide. Nitrous oxide is 298 times more active than carbon dioxide. Nitrous oxide is created as the result of soil and manure management processes. Methane also results from manure management processes and fermentation processes. As these gases also contribute to climate change effects, they can be considered as an extension of carbon management.

Climate Change and Carbon

In order to avoid climate change, there is a need to decarbonize our society and reduce the levels of global greenhouse gas emissions, particularly carbon dioxide, substantially. In the Intergovernmental Panel on Climate Change’s (IPCC) Fifth Report, it

is believed with a 95% level of certainty that human sources of carbon emission were the “dominant” force responsible for climate change since the 1950s. The report, which represents a synthesis of the most up-to-date data on climate change, presents a list of evidence that the air, oceans, and land are all unequivocally in the process of undergoing a change, with further rises in greenhouse gas levels contributing to increased warming and changes in all aspects of the climate system.

What is so concerning about climate change is that the present changes are unprecedented on time scales from “decades to millennia.” The tangible effects are warming of the land, sea, and air, the loss of ice from ice caps and glaciers, and an increasing in global average mean sea levels. Low-lying land is threatened by increases of sea level, which by 2081–2100, are projected to be in the range of 26–82 cm.

In order to reduce carbon emissions, we need to decrease the amount of nonrenewable fossil fuels that are burned. They release large quantities of carbon dioxide, which has been stored underground for millions of years.

This will involve significant technological and societal change. Fossil fuels, because of their energy density and versatility, are ubiquitous. So much of our society is dependent and reliant on the stable configuration of fossil fuels, the infrastructures used to process and distribute them, the technologies used to utilize them, and the institutions and companies which support their production, distribution, and use. Achieving a transition away from this configuration, to a low carbon economy, is no small feat.

There are many voices, however, who counter that we are unable to reduce the rate at which we emit carbon dioxide quickly enough to avoid some of the worst effects of climate change. Those who believe we are unable to make this transition quickly enough assert that other means will be required to reduce atmospheric levels of carbon, in order to avoid some of the worst effects of climate change.

It is argued that in order to reduce atmospheric concentrations of carbon dioxide further, we should invest in measures to “capture” carbon dioxide from the atmosphere or industrial

processes and sequester it underground. Some approaches to this problem entail significant technological and engineering input and deep geological storage. Carbon farming methods, by contrast, have the potential to be cheaper, storing carbon in the upper layers of soil.

Climate Engineering

Climate engineering is the process of deliberately intervening in the Earth’s climate system on a large scale through the application of geo-engineering techniques with the express intention of reducing the effects of climate change. There are two distinct approaches to climate engineering. One set of approaches focuses on reducing the levels of carbon dioxide in the atmosphere, while other methods focus on managing the levels of solar radiation reaching the Earth, to mitigate against higher levels of carbon dioxide in the atmosphere. Carbon farming methods fit in to the former series of approaches.

This is not seen as an alternative to emissions reduction but as a complimentary approach. Mitigation is seen as the primary key to addressing climate change (reducing carbon emissions), and there is also increasing acceptance that there may need to be a degree of adaptation to climate change. Geoengineering approaches like carbon farming are seen as a third and final approach.

Carbon Farming Methods

There are a number of methods which can be deployed in order to increase the soil carbon pool. These include restoration of the soil, regeneration of woodlands, no-till farming, crops which provide cover for the soil, management of soil nutrients, and the application of manures and sludges to ground. All of these approaches aim to conserve the quantity of carbon locked up in the pedosphere.

There are a number of specific approaches to carbon farming, which have received significant attention:

No-Till Farming

In traditional farming methods, the soil is tilled between crops. This is to say that the soil is

mechanically agitated – either by humans, draft animal power, or mechanical means. Soil microbial activity increases rapidly as a result of the exposure to air, and the inversion of different soil layers. This microbial activity leads to the decomposition of organic matter and the release of carbon dioxide into the atmosphere. It has been estimated that 78 billion metric tonnes of carbon emissions has resulted from the practice of tillage. That industrial agricultural practices have depleted the uppermost layers of cropland soils presents an opportunity – as the depleted nature of these soils makes them receptive to use as a carbon sink. In addition to preventing emissions of carbon, no-till farming also reduces emissions of nitrogen oxide, another greenhouse gas.

In place of the mechanical agitation of soil, no-till farming uses organic residues that result from previous crop cycles left on the surface of the soil, and methods of sowing and fertilization that can be carried out without disturbance to the soil.

This biomass becomes incorporated with the soil, improving its carbon content. There are other corollary benefits to no-till farming. It helps to combat soil erosion and also ensures that water and nutrients are retained in the soil.

Biochar

Biochar refers to the use of charcoal as an agent for soil improvement. The charcoal is produced from the pyrolysis of biomass, which has been grown specifically for the purpose. Burying this charcoal in the soil helps to sequester carbon emissions, with the objective that the process has a negative carbon balance. There are corollary agricultural benefits to this approach – the improved soil has the potential to be more fertile, productive, and resistant to disease. Early European settlers to the Amazon basin noted the incorporation of charcoal into the soils that they found and called this soil *terra preta de Indio*. This soil had charcoal, bone, and manure added to improve its fertility. Fragments of pottery and other human artifacts have led archaeologists to the conclusion that this soil was the result of human activity. It is unproven whether *terra preta* was deliberately created; however, it has been found to be more fertile than unimproved soil.

Desert-Based Carbon Farming

In order to address the concerns of those who feel that carbon farming methods could compete with or potentially compromise agricultural activities for food production, there is a significant body of knowledge to suggest that carbon farming efforts should be directed to land which cannot be used for other agricultural purposes.

It is estimated that a hectare of the plant *Jatropha* could capture 25 tonnes of carbon dioxide per annum when grown in desert or marginal conditions. There would also be other derivative benefits to growing *Jatropha* in the desert. Potentially, desert areas could become more habitable. Furthermore, the plants seeds can be harvested for biofuel production.

However, one of the barriers to this plan is the availability of desalination plants. Water, additionally, is a precious commodity, and production of clean water from sea water is an energy intensive activity in itself. Some have advocated an industrial ecology approach to this problem – using biomass grown as a result of desert afforestation projects, to provide the power for desalination in a self-sustaining circular process.

Reforestation/Afforestation

Reforestation is the process of restoring forests that have been destroyed, while afforestation is the process of establishing a new forest in a place where there has not been one before. As the trees grow, they absorb carbon dioxide from the atmosphere. However, this is a reversible process, as if they are later burnt, that carbon is released again.

Manure Management

Animal wastes result in the emissions of greenhouse gases. They also result in nuisance odors. Both of these problems can be brought under control by better management of animal wastes. Anaerobic digesters can be used to capture the gases produced by manure as it is digested. This gas, rather than entering the atmosphere, can be used to generate energy, which can be fed into the grid. The carbon dioxide that results from burning the gas has a diminished global warming potential compared to the methane and nitrous oxide captured from the digestate.

Economics of Carbon Farming

Climate change will result in real and tangible changes to the environments in which people will live. There are financial costs attached to the process of mitigating against and adapting to climate change. There are various markets, internationally, on which carbon can be traded. In those legislatures where carbon emissions reductions are mandated, carbon trading activity is often used as an alternative for those who find it impossible or uneconomical to meet their commitments. A ceiling is established for carbon emissions, which producers cannot exceed. Those who fail to reduce their carbon emissions are able to purchase “carbon credits” from projects that seek to capture carbon. Equally, projects in the developing world that seek to reduce carbon levels may be financed through carbon credits.

There is the potential for those engaged in carbon farming activity to realize revenues through the sale of “carbon rights” to the carbon sequestered in their project.

There is much criticism and debate as to whether carbon trading constitutes a fair, equitable, and efficient way of reducing carbon emissions. In particular, there are wide and varied concerns about deficiencies in the design of carbon trading, their propensity to be manipulated and gamed, and the potential lack of equity. Others advocate a “gate tax” on carbon emitting fuels as a more efficient way of meeting the aim of reducing carbon emissions. That said, emissions trading schemes do have the potential to create revenue streams for carbon farming projects.

Agricultural Access to Carbon Markets

There is an economic value to carbon mitigation. Markets have been established on which carbon can be traded between those who can offer the means to reduce carbon emissions or remove carbon from the atmosphere – and those companies and industries with a need to reduce carbon emissions, but who cannot meet their obligations. The discourse on carbon markets is vast; there are many challenges in designing effective systems for carbon to be accounted for and traded.

One of the relevant issues to those engaged in activities of carbon farming is how to access the

markets for carbon. Here, initiatives like the Carbon Farming Initiative act as the bridge between those who are able to sequester carbon through agricultural initiatives.

Another issue is that carbon markets value only carbon; they do not place a value on other environmental services. As we have already noted, there are concerns about methods of carbon farming for which economic maximization is the main goal with environmental conservation being treated as a secondary priority.

Concerns About Carbon Farming

While carbon farming is a potential solution to reducing atmospheric concentrations of carbon dioxide, there are also a number of concerns that wide-scale adoption of this practice could have other, unintended consequences. Another parallel debate, which we could consider at the same time, is the rush to production of biofuels as a carbon-reduction measure. Many of the consequences of both measures are similar.

If landowners simply seek to maximize profits from carbon farming, there is a concern that large monocultures will be created that will undermine ecosystem biodiversity. Carbon farming schemes that simply incentivize carbon sequestration without adequate land stewardship guarantees are likely to result in carbon farmers seeking simply to maximize profit, inevitably resulting in unsustainable agricultural practices.

Furthermore, there is concern that carbon farming could compete with food crops for land, leading to an increase in the prices of food, which could adversely affect many of those in poverty or close to the poverty line.

Some have advocated that carbon farming could be carried out on marginal land. However, while this land might not be wholly suitable for commercial agriculture, there are still a great many of the world's poor who are dependent on marginal land for their subsistence – using it to graze animals and carry out small-scale agriculture.

That said, there are also measures that can address these concerns while also yielding environmental benefits. Agroforestry is an approach, which combines agriculture and forestry, and has potential to be used in the context of carbon

farming. Here, the integration of trees with more traditional cropping systems can yield resilience to problems associated with soil erosion.

Other approaches suggest that carbon farming should be done in areas of land that are wholly unsuitable for agricultural purposes, eliminating concerns that this would then compete with food and other crops for land. It has been suggested that *Jatropha* could be grown as a carbon crop in dry coastal areas.

Benefits from Best Practice Carbon Farming

If there is an adequate framework of incentives and regulation, it is possible for best practice carbon farming to yield a plethora of positive outcomes: above and beyond the fixation of carbon.

Carbon farming practices have the potential to result in the restoration of ecosystem services. Best practice schemes may also promote carbon farming in concert with a number of other goals. Soil erosion can be prevented through the binding effect of plant root structures. The accumulation of organic matter or charcoal forming *terra preta* can also act as a soil restorative. Pollination and the bee population can be encouraged with the selection of suitable plants.

Carbon Farming Initiatives

There are a number of initiatives globally that seek to promote the practice of carbon farming.

One of the most notable carbon farming initiatives is the CFI, a scheme which allows for Australian Carbon Credit Units (ACCUs) to be earned from agricultural and forestry carbon farming projects. This scheme is administered in Australia by the “Clean Energy Regulator.” It provides for farming businesses to earn ACCUs through both schemes to reduce carbon emissions through sequestering carbon in soil – but equally, through avoidance of other greenhouse gases such as methane and nitrous oxide.

The scheme allows farmers to earn carbon credits if they follow a series of “approved methodologies.” These methodologies are in place to provide a robust assurance that the stated carbon aims will be achieved through the agricultural practice. There is an additional guarantee that these

methodologies are robust, as a result of external scrutiny from another department, the DOIC – the Domestic Offsets Integrity Committee.

Summary

With the latest climate science emerging from the IPCC’s Fifth Report, the anthropogenic origins of climate change are undisputed. The measures required to reduce carbon emissions worldwide in an equitable manner are tough. Carbon-reduction measures of the magnitude required will require substantial changes in lifestyles, the way we configure our societies, and the technologies we use to deliver the goods and services that we use.

It is for this reason that measures such as carbon farming, which can help mitigate against carbon emissions but have relatively small impact on many peoples everyday lives, are seen as seductive in their simplicity.

Undeniably, the twin pressures of resource scarcity and climate change will shape agricultural processes and practices in the years to come. Carbon farming potentially has consequential benefits when integrated with other agricultural practices – not only for the atmosphere but also for soil quality and the biosphere.

That said, there are also substantial risks involved. Providing subsidy and incentive mechanisms for carbon farming, without appropriate consideration of regulation, has the potential to lead to unforeseen impacts. We can see many parallels in the biofuels debate, where misguided subsidies have caused multifarious environmental and social problems. Incentives based on targets, without effective oversight, have the potential to lead to environmental destruction. Furthermore, there are also risks with the loss of productive agricultural land which could otherwise be used for food production. Carbon farming has the potential to encounter the same problems that biofuels have created in reference to food versus fuel.

That said, as the consensus regarding climate change becomes increasingly solid and immutable, the need for practical solutions

will become increasingly urgent. Carbon farming has a role to play in carbon reduction if well implemented.

Introduction

The ethics of care are a family of moral insights, theories, and practices that emerged in the past few decades as an alternative to dominant moral approaches. Their main ethical and political objective is to not lose sight of the experiences, activities, and works involved in caring. Since such concrete activities are deeply embedded in the everyday ordinary life, they are hardly objects of abstraction and for this reason they have been constantly neglected by moral and political mainstream theories. Although these ethics originated from feminist studies and activism, some scholars insist on the fact that a gender-neutral concept of care would be more effective in seizing the injustices that caregivers (both men and women) face in their everyday life (Laugier et al. 2009).

The above-mentioned dominant moral and political theories usually do not have much to say about food, which, as long as public health and basic rights are not menaced, is to be considered a matter of taste and free choice of consumers. Moreover, the moral issues related to food and personal relationships in the domestic sphere are hardly definable in terms of utility, rights, or justice, they are a matter of care. These approaches are blind to important aspects of the human relation to food. In the words of Michiel Korthals, “meals belong to the extremely vulnerable and valuable meeting points where informal relationships are intensified” (Korthals 2004). Nutrition in this sense is to be understood as a

caring activity as it is related to many forms of domestic care and nursing.

There are multiple ways in which nutrition can be a form of care for others. In different care situations such as mercy, romantic love, parental care, or feeding nonhuman animals, different foods carry specific meanings. Italian anthropologist Vito Teti, for example, describes the “cunsulo” tradition in the South of Italy. When a member of the community dies, the custom consists in the offering of prepared dishes for the mourning family that is not in condition to cook. Teti holds that the etymology of the word “companion,” from the Latin *cum* (together) and *panis* (bread), is paradigmatic of the social bond’s reinforcing function of nutrition (Teti 2015). Feeding one another is a caring task that creates and reinforces social bonds, precisely the kind of activity that the ethics of care seek to empower.

The caring aspects of human nutrition and the everyday life injustices embedded in such ordinary caring activities both suggest that the ethics of care represent a unique political and moral tool to grasp the relevant ethical dimension of food rooted in an ordinary ground that is anthropological rather than theoretical. This view will be applied firstly to the household to explore the morally problematic power relations hidden in the apparent ordinariness of meals. Secondly, these issues will be analyzed within North-South relations and development practices, and finally, it will be expanded to the nonhuman.

Intra-household Care

The ethics of care introduce a moral dimension of nutrition that is concerned with exploring the everyday emotions, experiences, or injustices felt by caregivers and care-receivers. Such dimension is particularly insidious because of it being part of the ordinary, of “the way we eat.” Questioning such experiences can lead to question our culture and what we perceive as perfectly natural and far from immorality.

Patricia Paperman and Aurélie Damamme have carried out a survey on the experience of ordinary domestic care-giving on French

women. The interviewed related their ordinary experiences of intra-household care-giving in which they experienced a sometimes-unbearable feeling of injustice, resentment, and even rage. Many of them clearly felt an asymmetry in their care relation, as while they were taking care of their family members, they felt the urgent yet unheeded need to be taken care of as well (Laugier et al. 2009).

The engagement of women in domestic care tasks, according to French philosopher Sandra Laugier, resulted in their exclusion from the public sphere. Those experiences are reduced to private feelings without any moral or political relevance. The main goal of the ethics of care is to reverse this trend by letting caregivers have a public voice, so that such private experiences get to be publicly expressed and heard. This process makes the intra-household ordinary sphere a political ground. By doing so, such apparently ordinary and trivial tasks can come to be considered real professions practiced by individuals with needs and a legitimate political voice (Laugier 2015).

In most human societies, women are occupied in food every day through a multitude of thoughts, dispositions, and activities. In fact, the caring task of preparing meals is often, in a morally problematic way, a feminine one (Reiheld 2014) that includes activities such as grocery shopping, setting up the table, cooking, doing the washing-up, and several other household chores. As Korthals puts it “food is therefore a gender matter par excellence” (Korthals 2004).

Men contribute (consciously or not) to maintaining the culinary task as exclusively feminine. This is the result of even the smallest gestures and daily rituals, such as not cooking because of “not knowing how to cook.” This reason (or even excuse) defines that the knowledge of cooking is restricted to women and is supposed to be transmitted from mothers to daughters. According to this cultural perception, caregivers (women) tend to adopt such role and find themselves obliged to learn and therefore take care of those who do not know how to cook. This is a simple example of a form of domination expressed through a daily routine. In order to illustrate this quotidian act, the French sociologist

Pierre Bourdieu argued that, besides from men waiting for women to prepare and serve them food, they tend to eat more – because it is a sign of virility – they spend more time at the table finishing their meals while women can begin cleaning up. He uses the example of the French dish *pot-au-feu*, which requires entire days of preparation, in order to prove the connection with the women who are entirely dedicated to domestic tasks and who are also called *pot-au-feu* in France. He argues that the cultural preference for such dishes is closely linked to the “androcentric desire to confine women within the domestic walls all day long” (Bourdieu 2013).

2- North-South Care

When it comes to food, caregivers are traditionally mostly women such as housewives, nurses, waiters, and cooks. However, in the Western societies there has been a major shift and these traditional roles have been taken over by immigrant workers. Even the production of “ethical” local foods as well as their distribution and preparation hides the invisible work of men and women who are more likely to accept poor working conditions and remuneration.

Care is still a feminine issue; it concerns more and more women from the South of the world both in their home countries where they are still tied to their traditional roles and in the north where they face the burden of the emancipation of wealthy white women. Given these assumptions, the nature of care has changed from its Western feminist origins to what has ironically been called a novel “Filipino” rather than “feminine” nature of care (Raïd 2009). Care-workers in Western societies who always confronted social and sexual stigma are now increasingly affected by racial prejudices and their political voices are cut out from the public scene in a systematic way because of their often precarious or even illegal conditions that deprive them from minimal constitutional rights.

Alex Tizon posthumously published an essay that perfectly exemplifies this clash of cultures. It is the story of how his Filipino descendent family hid for decades as slave in their apparently typical

American life. The author’s touching descriptions impeccably picture how care work is, on the one hand, easily unseen and how, on the other hand, the task of letting one’s moral sensitivity win over cultural normality is a rather tough one. Another interesting aspect of the narration is the role of meals in reiterating the condition of domination but also potential occasion to break the ordinary and showing mutual care and affection

Cooking was Lola’s only eloquence. I could tell by what she served whether she was merely feeding us or saying she loved us. (Tizon 2017)

Such constant work of care is made invisible, in this story as in many other cases, by gender-biased social norms, laws, and practices, and factors such as the architecture (i.e. the kitchen walls) and the economy as care chores are not paid nor recognized as a professional occupation or, in any case, not a reputable one.

These conditions, in which most women in the south of the world are living, are being addressed in the United Nations 2030 Agenda under Sustainable Development Goal number 5. Specifically under target 5.4: “Recognize and value unpaid care and domestic work through the provision of public services, infrastructure and social protection policies and the promotion of shared responsibility within the household and the family as nationally appropriate.” In fact, worldwide, women’s time is absorbed by several food and nutrition-related activities such as minding of children, fetching water and fuelwood, purchasing and preparing food, cleaning, and caring for the sick and the elderly.

The Food and Agriculture Organization of the United Nations (FAO) and the Asian Development Bank reported that the contribution of care to the market economy is considerable in Western countries, while it is immense in low-income countries such as India and Tanzania where it has been estimated to represent the equivalent of 65% of gross domestic product (GDP) if it were valued in monetary terms. This figure would represent 182% of Indian total tax revenue if unpaid care work were to be financed by the public purse.

This gives an idea of the considerable debt of society as a whole to women who perform the vast majority of this work— largely unpaid,

undervalued, and unrecognized. Modest as it is, this recognition of women's unpaid work does matter. It acknowledges the importance of care to the economy in general.

Moreover, Food and Agriculture Organization of the United Nations highlights the fact that such unpaid work is vital to maintenance of the agricultural workforce and therefore is key to food security as it represents a safety net of last resort in cases of hazards and social security failures (Food and Agriculture Organization of the United Nations, ADB 2013). Such considerations lead to a wider understanding, through a gender lens, of the close relation between care and food at a global level.

Nonhuman Care

Mainstream ethics and politics are grounded on the fiction of the autonomous and independent subject, which, besides unfortunate accidents, would need to be taken care of only at the beginning and at the end of her life. The ethics of care insist on the fact that we are all vulnerable and dependent on others as we all need to be taken care of in every moment of our lives. Moreover, care is needed by our societies. Meals are moments in which we face the frailty of life, the one of the animal that died to end up in our plate as well as our own vulnerability that is particularly visible, we are hungry, we are in need, and we need to be taken care of. Realizing this condition of dependence means to become aware of our relation of care toward the environment and nonhuman animals which share with us such vulnerable nature (Laugier 2015).

Berenice Fisher and Joan Tronto proposed a broad definition of care that grasps both the pervasive and elusive nature of the concept.

a species activity that includes everything that we do to maintain, continue and repair our world so that we can live in it as well as possible. That world includes our bodies, ourselves, and our environment, all of which we seek to interweave in a complex, life-sustaining web. (Fisher and Tronto 1990)

Such definition links the food aspects of care examined in the previous sections to the entities,

possibly moral entities that we eat and feed and on which we rely for our own nutrition. The ethics of care against anthropocentric (and androcentric) nature of Western thought and as an alternative to some rationalistic forms of animalist theory insist on the reciprocal moral relations that exist between human and nonhuman animals that is sometimes a personal, sometimes a practical relation (Laugier et al. 2009). Nonhuman animals can be mere objects of care repaying us with their work or their own body (agriculture, experimentation), but in many cases they clearly act as subjects of care even toward humans as, for example, in animal-assisted therapy (Le Goff 2012). Many species, in particular mammals, have been observed while taking care, interestingly this often happens through feeding, of other individuals even if not related or belonging to other species. In the words of Charles Darwin:

Capt Stansbury found on a salt lake in Utah an old and completely blind pelican, which was very fat, and must have been long and well fed by his companions. Mr Byth, as he informs me, saw Indian crows feeding two or three of their companions which were blind. (Rachels 1990)

Depending on the different species, individuals, and particular situations, humans find themselves involved in a multitude of different relations of care with nonhuman animals. Caring for a wild animal means to ensure its independence avoiding contact, which can still be a form of care. While nonhuman animals that live close to us and are part of our societies as pets or domesticated animals that we eat or that we feed and take care of were made more vulnerable and dependent by their evolutionary history of domestication and require active forms of care (Le Goff 2012). Moreover, following the definition of care, we can consider us having a relation of care with the environment that feeds us and that without our care would rapidly degrade.

The ethics of care, through ethology, literature, and the works of authors such as Coetzee and Cora Diamond, aim to expand human moral sensitivity to the nonhuman which is vulnerable and in need for care as we are (Laugier 2012). This vulnerability has been a main reason to create divisions between what can be properly subject

of the ethics and other entities which lack a political voice and for being more vulnerable can only be considered as passive moral patients with null or reduced agency.

The concept of “Human” creates the concept of nonhuman and tends to exclude certain social categories creating stigma, in the words of Judith Butler:

On the level of discourse, certain lives are not considered lives at all, they cannot be humanized; they fit no dominant frame for the human, and their dehumanization occurs first, at this level. This level then gives rise to a physical violence that in some sense delivers the message of dehumanization, which is already at work in the culture. (Butler 2004)

Martha Nussbaum shows how these marginalized social categories constitute twilight zones that separate human-dominant groups from their “animality,” their vulnerability (Nussbaum 2004). Western culture roots in the myth of the Eden; the first sign of incompleteness and vulnerability is a feminine one which is interestingly described through the act of eating. Stanley Cavell holds that women have been constructed through history as the living memory of men’s vulnerability (Raïd 2009). Women menstruate, give birth, receive the sperm, breastfeed, and feed men. All these activities which are linked to the continuity between animal life and mortality of the body are perceived as impure and contaminant generating taboos and stigma (Nussbaum 2004). The tasks of care constitute the perpetuation of our being mortal beings (Raïd 2009), that is why dominant groups have the psychological urge to constantly devalue and hide them in the domestic sphere; this also explains the blindness of dominant moral and political theories to the ordinary.

These considerations lead the theorists of care to insist on the fact that the failing of our dominant moral theories to fully include “the other” (women, Third World care-givers, non-human animals) as moral subjects does not mean that such entities lack some key mental abilities (i.e., moral agency) or that we lack some key mental abilities to grasp their thoughts and dispositions; it means that our theories are insufficient and need to be replaced with an Ethics centered on the attention to the need of “others” (human or not).

Conclusion

This entry has explored three different ways in which the ethics of care can represent a rich approach to explore aspects of our eating and food practices that often escape moral consideration. The ordinary nature of intra-household care grounded in context-specific feelings and cultural specific habits resist top-down moral abstractions; at global level such unpaid, undervalued, and unrecognized process eludes statistics and mainstream concerns neglecting the contributions of hundreds of millions of women’s to the economy, health, and food security of billions of people. This whole process can finally be unfolded by the acceptance of our vulnerability, which we share with the nonhuman, revealing that care sustains our world and that we all depend on the silent daily struggle of the other, the ones that bring food to our tables.

Carnism

Martin Gibert¹ and Élise Desaulniers²

¹McGill University, Montreal, QC, Canada

²Montreal, QC, Canada

Synonyms

Ideology of meat; Melanie Joy's view on food ethics; Opposite of veganism

Introduction

Carnism refers to the ideology conditioning people to consume certain animal products. It is essentially the opposite of veganism. The term was coined by social psychologist Melanie Joy (2001). She has fully developed the concept in further papers and in her book *Why We Love Dogs, Eat Pigs, and Wear Cows: An Introduction to Carnism* (Joy 2010). As the title of Joy's book suggest, people's relation to animals depends crucially on the species to which they belong: "We love dogs and eat cows not because dogs and cows

are fundamentally different – cows, like dogs, have feelings, preferences, and consciousness – but because our perception of them is different. And, consequently, our perception of their meat is different as well" (Joy 2010, p. 12).

A Descriptive Concept with a Normative Import

The primary goal of the concept of carnism is to describe a psychological fact: the perception of animal products as food is highly cultural. Indeed, different cultures categorize species differently: contrary to occidental habits, some Koreans regularly eat dogs, while in India, cattle who till soil and produce milk are perceived as inedible. In this basic sense, carnism is the generic name, which gathers all of the different ways people attribute edibility. Of course there is a gap between real edibility and perceived edibility: human beings are omnivores – they can eat the flesh of almost all animals (including human flesh). But they do not. In fact, the eaten species appear to be very few when compared with all the species living on Earth. Westerners, for instance, eat – on a regular basis – only a dozen species (mainly herbivores) among the millions of species of mammals, birds, fish, reptiles, and amphibians on the planet.

While recalling the gap between perceived and real edibility, the concept of carnism also suggests that there is nothing inevitable about Koreans eating dogs, Indians not eating cows, or Westerners eating pigs but not dogs. Here begins the normative use of carnism. Indeed, being largely unaware of the inherent cultural influence on perceived edibility prevents people from changing their food habits. This is why Joy considers that carnism is an exemplification of an ideology, i.e., a "shared set of beliefs, as well as the practices that reflect these beliefs" (Joy 2010, p. 29).

In this sense, veganism is also an ideology. Ethical vegans, for instance, believe that it is unethical to consume animal products (usually for animal welfare/rights or environmental concerns) and follow the particular practice associated with these beliefs: in a restaurant they will chose the veggie burger instead of the beef burger.

So, they chose not to eat meat. Joy formulated the idea of the concept of carnism when she noticed that there was no word to name the opposite ideology: people who choose to consume animal products and believe that it is the right thing to do. The best candidate, “omnivore,” was not an option because it denotes a biological disposition but not a set of beliefs. Moreover, vegans are not different from omnivores in the biological sense, so Joy thought a neologism was needed. She coined “carnism” from the Latin radical “carn” meaning “flesh” or “of the flesh” (carnism includes the consumption of eggs/dairy).

If veganism and carnism are both ideologies, they are, however, opposed in important ways. People who endorse veganism do so knowingly; people who endorse carnism are usually unaware of doing so. Indeed, an ideology is not always visible – the ideology of patriarchy is a prominent example. For thousands of years, men and women believed that masculinity was somehow “better” than femininity. It followed from this that men had more social power than women. It was an invisible ideology and one that still exists. A great achievement of the feminist movement is having brought attention to the existence of patriarchy and making its effects visible. Prior to the efforts of the feminist movement, patriarchy’s existence in society was the status quo, rarely questioned and almost never challenged. The same can be said for carnism: this ideology is so entrenched, it is so pervasively widespread in human societies, that it is largely ignored.

Social norms favor and reinforce the consumption of animal products and this is the mainstream way of life. By contrast, vegetarians and vegans are sometimes stereotyped as hippies or people with eating disorders, and they often trigger defensive reactions: “they are called hypocrites if they wear leather, purists or extremists if they don’t” (Joy 2010, p. 105). Consuming animal products is also valued because it is supposedly “natural” (which is a naturalistic fallacy because the fact that humans are omnivores is not a justification to any normative claim) and necessary for good health (despite overwhelming evidence to the contrary). As in the case of patriarchy, all of these justifications concur to present carnism as

normal, natural, and necessary. It appears to be an inevitable system and not a challengeable ideology.

For Joy, there is another important opposition between carnism and veganism. It is a normative one. Carnism – like patriarchy – is a violent and oppressive ideology; veganism is not. Indeed, this has been the basis of the animal rights movement for the last 40 years. Even if there are differing views in animal ethics, the fact that animal agriculture and slaughtering are violent practices is usually not controversy. “Contemporary carnism is organized around extensive violence. This level of violence is necessary in order to slaughter enough animals for the meat industry to maintain its current profit margin. The violence of carnism is such that most people are unwilling to witness it, and those who do can become seriously distraught” (Joy 2010, p. 32).

Hence, it could be said that carnism is a descriptive concept with a normative import. By naming a psychological fact – the perception of meat and animal products depends on a pervasive ideology – the concept of carnism makes people aware of it and allows them to challenge their perceptions and therefore move away from the violence in their lives that had before seemed inevitable. To say otherwise, showing that edibility depends on culture sheds light on an additional point: perception of edibility is morally arbitrary. Pigs deserve no more than dogs to be eaten. (For a similar view stressing the analogy between puppies and pigs, see Norcross 2004.)

Thus, the concept of carnism allows to change perspective. Beside the question “Why are some people vegan?” appears this new one, “Why some people are not?”

How Carnism Works: Explaining the Moral Inconsistency

The title of Melanie Joy’s book exposes a kind of inconsistency: people care for dogs and empathize with them while ignoring the suffering of pigs and cows. Putting aside some psychiatric disorders like psychopathy, empathy is a widespread human faculty, and there is neurological evidence

that people feel empathy toward animals (Filippi et al. 2011). So, the question is not why people empathize with dogs, but, rather, why they don't express empathy toward pigs and cows. In a certain sense, understanding how carnism "works" consists of understanding this lack of empathy toward certain animals.

Omission is probably the central explanation: "The ten billion animals that are killed every year for meat and the virulent consequences of contemporary animal agricultural practices remain conspicuously absent from public discourse" (Joy 2010, p. 102). But this omission does not mean that people are completely ignorant of the reality of factory farming and violence toward animals. "Common to all violent ideologies is this phenomenon of knowing without knowing. And it's the essence of carnism" (Joy 2010, p. 70).

According to Joy, there are several psychological mechanisms, which she identifies as psychic numbing (Slovic 2007) or "primary defenses" of carnism (the secondary defenses are justifications, like those described in part 4). They come in several ways. Objectification consists of viewing animals as things: for instance, in calling a chicken a broiler or steers beef. Deindividualization consists of viewing animals as abstraction. Finally, dichotomization allows people to put animals in categories like pets and farmed animal or cute and ugly.

However, all those interested in moral inconsistencies do not arrive at the same conclusions as Joy. Studying the animal-human interactions (or "anthrozoology"), the psychologist Hal Herzog considers that contrasting attitudes toward animals reflect merely different moral intuitions that may be triggered by different moral heuristics (Herzog and Burghardt 2005). They are not anomalies or hypocrisies, nor are they caused by an invisible ideology or a lack of empathy. Rather, they are part of human nature and somewhat inevitable. They are an "unavoidable result of the perennial tug of war between the rational part of us and the yahoo within" (Herzog 2010, p. 239). Herzog even acknowledges these inconsistencies in his own behaviors: "The yahoo [My intuition] tells me that the exquisite taste of slow-cooked pit barbecue somehow justifies the death of the hog

whose loin I am going to slather with a pepper-based dry rub" (Herzog 2010, pp. 255–256).

Working from Herzog's theory that empathy is not the default attitude toward animals, the question of why people love pets must then be addressed. A possible explanation comes from the "cute response" which could trigger parental instincts (Sherpell 2002). Indeed, pets often share features with human infants: large foreheads and craniums, big eyes, bulging chicks, and soft contours. Animals that are eaten, on the other hand, often lack this cute factor. Another interesting explanation of inconsistent empathy responses could derive from disgust (Ruby and Heine 2012) or food taboo (Fessler and Navarrete 2003).

However, recent experimental studies tend to confirm Joy's view. For instance, it has been shown that categorizing an animal as "food" may diminish their perceived capacity to suffer, which in turn dampens moral concern (Bratanova et al. 2011). When people are asked to eat dried beef instead of dried nuts, they show less moral concern for cows and animals in general (Loughnan et al. 2010). This can be analyzed in terms of cognitive dissonance. Indeed, people do care for animal but they also enjoy their meat. One way to reduce this dissonance is to deny that animals suffer and are sentient. Thus, in an insightful study, Brock Bastian and his colleagues showed that people attribute less mental capacity to a cow (or a sheep) when the animal was described as being bred for meat consumption as opposed to having been bred for a different purpose (Bastian et al. 2012).

Finally, a link between racism, on the one hand, and speciesism or carnism, on the other, has been experimentally established. For instance, children's human-animal divide beliefs predicted greater racial prejudice, an effect explained by heightened racial dehumanization (Costello and Hodson 2012). The study of people's relationship with animals, especially the ones chosen to like and to eat, is still fairly new. But it appears to be a fascinating and blossoming field, which will surely also be improved by the new understanding of the psychology of vegans and vegetarians (Ruby 2012).

Origin and Debates

The name “carnism” is a neologism, but the ideas behind the word are not brand new. As early as the first century BC, the Greek essayist Plutarch tried to shift the perspective on vegetarianism in his “De esu carniū” (On Eating Meat): “Can you really ask what reason Pythagoras had for abstaining from flesh? For my part I rather wonder both by what accident and in what state of soul or mind the first man who did so, touched his mouth to gore and brought his lips to the flesh of a dead creature, he who set forth tables of dead, stale bodies and ventured to call food and nourishment the parts that had a little before bellowed and cried, moved and lived” (Plutarch 1957, p. 541).

So, for Plutarch, what is really surprising is not why some people do not eat flesh but why so many do. He also sheds light on many inconsistencies and false beliefs surrounding animals used for food; for him, eating flesh is no longer a necessity and is not natural for human beings. Indeed, in a remote past, our ancestors may have had no choice but to eat flesh, but the progress of agriculture now makes it superfluous. People also think that they are naturally designed to eat meat. But this is false, replies Plutarch in this oft-cited excerpt: “If you declare that you are naturally designed for such a diet, then first kill for yourself what you want to eat. Do it, however, only through your own resources, unaided by cleaver or cudgel or any kind of axe” (Plutarch 1957, p. 553). Of course, Plutarch could not use the modern concept of ideology. But his identification of false beliefs and his attempt to understand their origin and the ways in which people endorse them surely makes him one of the main precursors of the concept of carnism.

More recently, many authors in the field of animal ethics have raised similar concerns. Already in the 1975 preface of his work *Animal Liberation*, Peter Singer noticed the importance of mental habits, which slow down the moral progress for animals. “Habit. This is the final barrier that the Animal Liberation movement faces. Habits not only of diets but also of thoughts and language must be challenged and altered” (Singer 2009, p. 13).

Singer is well known for having brought the term “speciesism,” a concept close to carnism and coined by the psychologist Richard D. Ryder, to the fore. Speciesism – analogous with racism or sexism – means an assignment of moral considerability to individuals solely on the basis of their species. For Singer, this is the basis of a discrimination which is morally arbitrary – just like discriminations based on race or sex are morally arbitrary. (Singer, following the preference utilitarianism, considers that interests of individuals should be the only basis for moral discrimination.)

How then are speciesism and carnism to be distinguished? First, speciesism is broader than carnism. For instance, you can be vegan and consider that no animals deserve to be exploited for food or leather but still morally value the life of a horse more than that of a cow because of their belonging to a hierarchically lower-ranked species. In this case, you are probably not a carnist but, in a sense, you are still a speciesist.

Theoretically, it is possible to be speciesist in according more value to a given species than to the human one, but, most of the time, it means to place humans at the top of the hierarchy and use this first place to justify using other animals for food and to continue exploiting them. So a carnist is a speciesist who focuses his/her attention on certain species (like pigs or cows), assigns them less value than to other species (like humans or dogs), and acts accordingly (eats pigs and wears cows). Carnism is a kind of applied speciesism – and much more easy to identify. Joy puts the distinction this way: “Carnism is the ideology in which it’s considered appropriate to eat some of the animals on the lower rungs of the speciesist hierarchy. Carnism is a “sub-ideology” of speciesism, just as anti-Semitism, for instance, is a sub-ideology of racism” (“Carnism Frequently Asked Questions”).

But it seems that there is also a more subtle or connotative difference between the two concepts. Carnism describes an ideology: it is something entrenched and embodied which affects the way people perceive animals and food in practice. Speciesism refers to a normative theory: it is a justification of certain value assignments. So,

carnism can be interpreted more as a psychological concept and speciesism as a philosophical one. It also seems possible to consider the two concepts as the two sides of the same coin: the descriptive and the normative. In the latter sense, one could perceive and behave as a carnist but think and conceptualize as a speciesist.

Some have criticized the concept of carnism because it could be confusing, etymologically and ethically. Indeed, even if Joy defines carnism explicitly as the opposite ideology to veganism, the Latin radical “carn” draws attention to flesh. But people who do not eat flesh are vegetarian, not vegan. However, for Joy, people who believe that consuming animal products (like milk or leather) but not meat is okay are – at least to a certain degree – carnists. It is also true that to illustrate carnism, Joy examines food questions (including milk and eggs) or animal product consumption (like leather), but no other forms of animal exploitation such as animal experiments or animals used in entertainment. Ethical vegans, therefore, can reject the concept of carnism on the basis that it is misleading because it is not the exact negative of their view – for which they still have no name.

This kind of critique comes mainly from the abolitionist approach in animal ethics. Indeed, this approach claims that all animal exploitation should be abolished (focusing especially on the current acceptance of animals being considered property) and recognizes some basic rights for animals. It is classically opposed to the welfarist approach, the focus of which is on animal welfare rather than rights. Now, some abolitionists tend to consider carnism as a welfarist tool or concept. For instance, the leading abolitionist advocate Gary Francione denounces what he calls the “invisibility” position, that is to say, the “claim that the ideology that supports animal exploitation is ‘invisible’” (Francione 2012). He reproaches this position to “relieve us from moral responsibility for our conduct, claiming that if we participate in animal exploitation, it’s because we are being ‘victimized’ by the ‘invisible’ ideology” (Francione 2012).

It should also be noticed that Francione talks about “moral schizophrenia” to qualify the fact that people can condemn dog fighting while eating meat or that hunters can rescue a deer but kill

the same one a month later when the hunting season is opened. Thus, moral schizophrenia points out that “we do not think clearly about our moral obligations to animals” (Francione 2007). Francione appears to criticize less the descriptive dimension of carnism than its normative import. It is not clear, however, why reasoning in ideological terms rather than in terms of moral schizophrenia should lead to welfarist rather than abolitionist positions.

Neocarnism: A New Wave of Justifications

Neocarnism refers to a new wave of pro-meat and anti-vegan arguments (Joy 2011). Thanks to the ease of accessing information on the Internet and the growing public awareness of the way consumed animals are treated, it is less easy to deny the harm that is caused to them. The first defense of the carnistic ideology, invisibility, therefore leaves room to justifications as secondary defenses. The neocarnistic arguments allow conscientious consumers, who begin to question their carnistic habits, to refrain from abandoning altogether their omnivore practice and to find reasons to feel good about maintaining it.

Joy identifies, among others, three neocarnistic discourses aimed at responding to animal welfare/rights and environmental and human health arguments. The first discourse holds that veganism is too extreme and that people would be better off consuming “humane” or “happy” meat. In this sense, this discourse tries to conciliate compassion toward animals with carnistic practices. A second line of defense, “ecocarnism,” addresses environmental concerns by praising small-scale farms producing local and “sustainable” meat. Joy notices that it is also argued “that people’s aversion to killing animals is a modern aberration; veganism is seen as a contemporary movement of upper-middleclass urbanites and suburbanites who have become ‘soft’ and disconnected from nature” (Joy 2011). The third discourse stresses (against a wealth of strong evidence) that consuming animal products is a necessity for health reasons and that this overrides any moral reasons not to consume

animal products. In the end, these discourses remain carnistic, because they do not truly challenge the cultural perception of animal products as food – they simply provide new justifications.

This is why Joy also describes neocarnism as a backlash against veganism; neocarnistic arguments “are signs of society’s willingness to examine the ethics of eating meat, eggs, and dairy, and they reflect people’s genuine concern for animals (and the environment and health). But they also reflect the resistance of the dominant, meat-eating culture to truly embracing a vegan ethic” (Joy 2011).

Summary: Carnism and Moral Perception

To conclude, it should be recalled that carnism does not refer to a clear-cut and monolithic ideology. American carnism is not the same as the French or Chinese manifestations of this ideology. Moreover, if carnism and veganism are opposite ideologies, they also stand on a continuum with neocarnism and vegetarianism between the two ends. Therefore, it is possible to be more or less carnist. Or, in a slightly different way, it can also be said that there are some prototypical and atypical instances of carnistic practices and beliefs. In this regard, the fact that the etymology (pointing to flesh) does not extensively define the concept reflects merely this kind of radial structure.

Carnism has been presented as a descriptive concept with a normative import. Naming and describing an ideology allows people to contest it. Thus, from a metaethical perspective, the concept of carnism could be interpreted as a tool for moral knowledge. So, how does this work? If moral knowledge is defined as the set of morally relevant beliefs about a situation, mastering the concept of carnism may surely improve moral knowledge because it makes people aware of many false beliefs (for instance, that eating meat would be natural, normal, and necessary). This is why a descriptive concept, like carnism, can possess a normative import: by improving moral knowledge.

More precisely, and from a moral psychological perspective, it may be said that a large part of this improvement operates through moral perception.

This step of cognitive moral process, often overshadowed by the next step of moral judgment, is still crucial, as explains Lawrence Blum:

An agent may reason well in moral situations, uphold the strictest standards of impartiality for testing her maxims and moral principles, and be adept at deliberation. Yet unless she perceives moral situations as moral situations, and unless she perceives their moral character accurately, her moral principles and skill at deliberation will be for nought and may even lead her astray. In fact one of the most important moral differences between people is between those who miss and those who see various moral features of situations confronting them. (Blum 1991, p. 701.

Now, carnism as ideology may succinctly explain this kind of difference in moral perception of animals. For instance, seeing a cow as something rather than as someone could carry important moral significance. Further to this, considering carnism leads people to question their moral perception and to pay attention to moral psychology. This is certainly an interesting aspects of this concept, which is less a philosophical one (like speciesism) than a moral psychological one.

Finally, and from a normative theory perspective, the concept of carnism could be related to virtue ethics. Of course, deontologists and consequentialists may be interested by questions of moral knowledge, but by focusing their attention on the agent (rather than on the action or on the consequences of the action), virtue ethicists seem more concerned with understanding, promoting, and discouraging certain kinds of moral perceptions. To that extent, Joy’s work may be interpreted as an insightful and useful contribution to a neglected area of animal ethics.

Introduction

In recent years there has been a proliferation of guidelines related to child health. Prominent among these are guidelines on child nutrition. Guidelines cover a large range of questions relating to child nutrition, from duration of breast-feeding and supplementary feeding in infancy to weaning, establishing healthy eating in toddlers, and meeting the nutritional needs of children at various stages of development.

Guidelines are used in professions such as medicine as a means of communicating evidence-based statements about best practice and encouraging quality improvement and reduction of unwarranted variation in practice. There is significant debate about the authority of professional guidelines, and in particular questions are raised about the conditions under which divergence from guidelines is permissible. Many child nutrition guidelines are ultimately intended to influence parental, rather than professional practice. The practices that child health nutrition guidelines address occur within the private sphere and relate to feeding practices that may carry deep cultural and familial significance. The status and authority of guidelines directed at families is even less certain than in the case of clinical guidelines. Child nutrition guidelines can be viewed not simply as pieces of advice that parents may act upon according to their own judgment but as assertions of best practice against which parental practice is evaluated. Child nutrition guidelines can inform parental assessments of their own practice and those of others, and as such they become instruments for attributions of praise, blame, and the moral emotions of pride and guilt. The feelings of guilt and shame that many women who do not breast-feed for the recommended period report illustrate the power that guidelines have to set effective parenting standards.

The standard-setting dimension of guidelines raises a number of ethical issues including concerns about the normative status of guidelines, resourcing in support of adherence and industry influence and the integrity of guidelines. This entry will introduce clinical guidelines, describe the relevant differences between clinical

guidelines and those that target parental practice, and address each of the ethical issues indicated above.

Clinical Guidelines

Clinical guidelines have become an increasingly common feature of the medical practice landscape since the 1980s. The Institute of Medicine (a division of the National Academy of Sciences that provides independent advice to decision-makers and the public about matters relating to health) offers the following definition:

Clinical practice guidelines are statements that include recommendations intended to optimize patient care that are informed by a systematic review of evidence and an assessment of the benefits and harms of alternative care options. Rather than dictating a one-size-fits-all approach to patient care, clinical practice guidelines offer an evaluation of the quality of the relevant scientific literature and an assessment of the likely benefits and harms of a particular treatment. This information enables healthcare providers to proceed accordingly, selecting the best care for a unique patient based on his or her preferences (IOM 2011, p. 1).

The rise of clinical guidelines is a response to a number of developments. Scientific research has increased in quantity and availability, but it is difficult for clinicians to keep abreast of emerging research and to assess its implications for practice. Alongside this, there is strong demand for improved quality of care and reduction of unwarranted variation in quality and availability of care provision. Guidelines encapsulate the existing evidence about a defined question and draw recommendations for clinical practice out of that evidence. In this way, they make evidence accessible to clinicians and support greater consistency of care, not by eliminating variation but by providing an evidence-based standard against which decisions about patient care can be reached. The idea is that variation in care will not reflect inaccessibility or misinterpretation of relevant evidence, but will instead reflect professional and patient discretion in individual circumstances.

Clinical guidelines have excited controversy on a number of grounds. They have been identified as a means of rationing care and limiting the over-treatment associated with defensive medicine. They have also been seen as a means by which sub-specialties may attempt to claim clinical territory. A large industry in guideline generation has emerged, with guidelines being issued by a wide variety of professional bodies, scientific institutes, employers, and other organizations. In some areas of practice, they have multiplied at an astonishing rate. Some have been found to contain conflicting or misleading statements. The development process has undergone considerable scrutiny. There is also debate about the use of guidelines as evidence in court proceedings for medical negligence or malpractice. A guideline may be used as a “sword” by which to inculcate clinicians if they fail to adhere or as a “shield” to exculpate a clinician whose practice complied with a guideline. The matter of how courts should regard guidelines has been discussed in medico-legal literature (Tingle and Foster 2002).

The Status of Clinical Guidelines

The IOM’s definition makes clear that guidelines are intended to permit variation, in deference to professional expertise and in recognition of the need for discretion to which variation in clinical circumstances gives rise. Guidelines are not rules that must in all instances be followed. But neither are they wholly optional. Guidelines occupy an uncomfortable middle-ground between rules and advice.

When a rule is issued by a legitimate authority acting within its sphere of authority, the rule creates an obligation in those to whom it applies. The rule-maker is entitled to demand compliance and to hold violators to account, possibly reprimanding or imposing punishment for noncompliance.

In contrast, advice, as classically construed, can be characterized as the supply of non-enforceable reasons for action. In giving advice, an advisor implicitly acknowledges that the advisee is entitled to act according to his or her own judgment in this matter and that the advisor is not in a position of control. Unlike rule-makers,

advisors cannot legitimately enforce compliance with their advice nor hold advisees to account. Advisees can reject advice without owing an explanation to their advisors.

The claim to professional consideration that guidelines assert is greater than the claim associated with advice. Arguably, clinicians are obliged to keep up-to-date with guidelines issued by relevant authoritative sources (such as professional bodies and employers), to consider them and to employ them in clinical deliberations. Professionals may be held to account for non-adherence, in the sense that they must be willing to justify divergences. Clinical guidelines issued by authoritative sources command a greater attention than advisors are permitted to demand for their recommendations. But, unlike rules, they do not command “obedience.” Failure to adhere with a guideline would only constitute grounds for reprimand or disciplinary action if the relevant professional was unable to justify nonadherence and an adverse outcome had resulted.

Clinical guidelines vary in the authority of their contents and their provenance, and their claim to professional consideration varies correspondingly. The authority of a given guideline in a given clinical circumstance will often be a matter of debate, but it is clear that medical professionals are not free to disregard clinical guidelines entirely. Professional status and the privileges associated with it are earned and maintained through demonstrated satisfaction of professional requirements. The trust that the public places in professionals is parasitic upon public trust in the regulation and maintenance of standards by professional bodies such as medical colleges, councils, and licensing boards and employers. This entitles these bodies to set standards governing practice and to identify and foster given goals and values within the profession. Professional bodies are entitled to impose rules upon their members, discipline violations, and strip unsuitable individuals of their professional status. Guidelines, even when issuing from authoritative sources, are not the same as rules, but they can be the subject of rules: the United Kingdom’s General Medical Council’s *Good Medical Practice*

guide stipulates that “You must be familiar with guidelines and developments that affect your work” (GMC 2013, p. 6).

Guidelines for Child Nutrition

Child nutrition guidelines occupy more uncertain territory still with respect to their authority. Some child nutrition guidelines are directed primarily at professionals, because they relate to clinical matters (such as perioperative fasting, food allergy, or nutritional support of a seriously ill child). Many others are intended to inform parental, rather than professional, practice. Some such guidelines comprise technical assessments of evidence to inform professional advice to parents; others consist of simplified summaries of evidence and include recommendations aimed directly at parents. Many health-related governmental agencies issue child nutrition guidelines, although, tellingly, some prefer term such as “advice,” “tips,” or “recommendations” to “guideline.” The focus here is on those guidelines that are intended to inform parental practice.

Similar factors informing the increase in clinical guidelines apply in the context of child nutrition. Scientific evidence about nutritional risk and protective factors is increasingly available but its implications for child nourishment are not easily discernible by parents. Guidelines provide a means of gathering together evidence and distilling it into practical recommendations. Child health guidelines share with clinical guidelines the aim of reducing unwarranted variation in practice. Some parental practices reflect a lack of information and understanding of child nutrition; guidelines can help to eliminate variation that reflects a lack of understanding, rather than considered parental choices.

Like clinical guidelines, child nutrition guidelines are not a set of rules. As such they accommodate and acknowledge parental discretion. But, as with clinical guidelines, child health guidelines are aimed at persons who are not free of duties with respect to the matters they address. The duties that underpin parenting have implications for the status of guidelines.

The assumption of care for a child carries both moral and legal duties. There is a great deal of controversy about what duties parents have and about how, and if, they should be enforced. The Best Interests Principle, contained in Article 3 of the United Nations' Convention of the Rights of the Child and enshrined for use by courts and child protection agencies in many jurisdictions, including England and the United States, is too demanding and contestable to apply in any literal way to all familial activities and parental practices. This is so even if the focus is on the content of the moral duty, rather than its enforcement. Parents are morally permitted to make decisions that fail to optimize a child's interests in order to serve a legitimate end, as long as that child's interests are served "well enough." The claim that parents have a moral duty to protect and promote their children's interests to a "minimally adequate" level is tenable (Archard 2004). However, what counts as "minimally adequate" is contestable. As child nutrition is shown to have potentially profound implications for health and functioning throughout life, child nutrition practices could be drawn into the orbit of parental duty. But whether parents have a duty to attend to child nutrition guidelines is less clear.

If guidelines encapsulated parental duty, there would, by extension, be a duty to attend to them. But it is not clear that child nutrition guidelines are intended to, or do, follow the contours of parental duty. Guidelines could be statements of best practice, as discernible by reference to scientific evidence. If parents are not duty-bound to adopt best practice, attendance to them may be purely discretionary. However, clinical guidelines are often regarded as statements of best practice, but attendance to them is not purely discretionary: clinicians must keep up-to-date with relevant guidelines and be willing to defend divergences. Might parents also have a duty to refer to guidelines, to reflect on them, and to be willing to defend divergences, even if this is not a duty that the state should, or would attempt to, enforce?

Clinical guidelines are subject to a duty of attendance rather than one of compliance. This duty is imposed by professional bodies (including employers). If child nutrition guidelines are subject

to a duty of attendance, rather than one of compliance, where does this duty stem from?

Here there is a relevant difference between child nutrition guidelines and clinical guidelines. Clinical practice is governed by both professional bodies and employers, and their authority to set standards governing clinical practice is established. Parents do not become parents through admittance to a professional organization, membership of which entails acceptance of its authority. Arguably, parental duties arise from undertakings to one's child, rather than to an authorizing body. If parents have a duty to attend to guidelines, it must be either because their duty to their child entails this or because it has been imposed by an authorized third party.

The state has the authority to impose duties on parents. States are widely acknowledged as having a role as protector of vulnerable members of society, including children. This is often referred to as *parens patriae*: a Latin term meaning "parent of the nation." This role entails the state's right to assume control where necessary to ensure that children receive adequate care. The state is empowered to pass laws that constrain parental choice, on the grounds of the interests of the child. Laws requiring use of child safety restraints in motor cars and prohibiting physical chastisement of children (as in New Zealand) and smoking in cars containing children (as in Australia and some states in the United States, such as Arkansas, Oregon, and Maine) exemplify the exercise of this power.

Currently child nutrition guidelines do not have formal legal standing and are unlikely to receive it, unless there was a clear case that failure to adhere to a given guideline was associated with a demonstrable and serious harm to children.

Unlike clinical guidelines, child nutrition guidelines are not made the subject of an explicit duty by an external, authorizing body. The inherent contestability of parental duties means that whether there is a moral duty to attend to guidelines, or to comply with a specific guideline, is also contestable. As it currently stands, child health guidelines are more akin to pieces of advice, subject to parental evaluation and discretion, than they are to rules. But that does not

prevent them from exerting significant moral and social force on parents and particularly upon mothers.

The Normative Status of Child Nutrition Guidelines

Although a noncontroversial account of parental duties eludes philosophers and states, parents typically want to do a good job and look for sources of support and information to this end. While the status of child nutrition guidelines and the relationship between them and parental duties are unclear, they still exert a palpable force upon many parents and upon social understandings of good parenting.

Advice is directed at parents from myriad sources, particularly during pregnancy and the early years of parenthood. It is common for parents to exchange and discuss information relating to their children, and standards, norms, and expectations can be set not only through direct advice-giving but also when information from a third-party source is relayed (“my midwife says,” “have you read the latest advice about fructose? . . .”) and when parents relate their own practices to other parents (Fuligni and Brooks-Gunn 2002). Ideas about parenting are not only relayed in conversation but established through experience from childhood onward (Mechling 1975).

Mothers do the bulk of the heavy work when it comes to sourcing, fielding, assessing, sharing, and acting upon advice about child health (Kukla 2006). While role sharing is now more common and although power and resourcing does not always accompany responsibility, women are still more likely to be assigned primary responsibility for children’s diets. Of course, the women who oversee these aspects of childcare are not always, or only, mothers: grandmothers, mothers-in-law, aunties, and other senior female figures have significant influence in many social contexts (Richards et al. 2013).

Motherhood is a normatively charged identity category, associated with powerful and deeply rooted ideals. The controversy surrounding philosophical accounts of parental duties has not

produced widespread unwillingness to judge parents. Rather, multiple, sometimes conflicting ideals circulate, facilitating moral maternal evaluation and self-evaluation.

In societies where scientific knowledge carries a credibility premium, child nutrition guidelines have special force to set effective parenting standards. They offer the promise that adherence represents best practice, as identified through an objective and rigorous process of scientific discovery and evaluation. Health-care professionals and childcare workers use child nutrition guidelines to advise mothers, affirming their practice when it adheres to guidelines and encouraging change when it diverges. The fact that a practice is recommended in guidelines can be cited in defense when others question or criticize maternal practice, for instance, for diverging from tradition. Mothers may feel guilt, self-blame, and a sense of failure when they fail to fulfill guidelines or may feel the need to rationalize the failure, perhaps emphasizing the changeability of advice as a sign of its unreliability. Women’s sense of their own performance as mothers, and of their standing in the eyes of others, can be powerfully affected by the advice that circulates around them. The standing of child nutrition guidelines as definitive statements of best practice elevates them above other sources of advice for many parents: they are standards worthy of adoption, and mothers may be evaluated upon that basis.

The promulgation of the message that “breast is best” illustrates the prominence and power of child nutrition guidelines. Numerous studies report that this message has achieved wide recognition and influences feeding intentions and women’s feelings of pride if breast-feeding goes well, and guilt and shame if they elect not to breast-feed or do not continue to feed for the recommended time frame. But guilt and shame can also accompany breast-feeding, given societal expectations of modesty and associations between breasts and sexuality (Taylor and Wallace 2012).

Despite the social mores women navigate, the evidence in favor of breast-feeding is presented as definitive: breast-feeding offers babies the best possible start in life, and mothers are judged on their willingness and ability to give their children

the best possible start in life (without infringing upon the expectations of others).

Some women report feeling pressured to breast-feed (Hoddinott and Pill 2000) and use of terms such as “successful breast-feeders” compounds the normative force of these guidelines (Burns et al. 2010). Breast-feeding guidelines also apply in antenatal care and midwifery. Hospitals, health providers, and professional bodies may adopt policies and guidelines that require clinicians to promote breast-feeding and reduce women’s access to support with bottle-feeding. Some midwives report “breaking rules” in order to support mothers who choose to or require bottle-feeding (Furber and Thomson 2006).

While guidelines formally preserve parental choice with respect to child nutrition, they can exert significant pressure, influencing parental perceptions of available choices and attributions of praise and blame. Moreover the reasons that child nutrition guidelines are not adhered to are not necessarily reducible to parental choice (Kukla 2006).

Supporting Adherence to Child Nutrition Guidelines

The purpose of child nutrition guidelines is to enable mothers to make evidence-based decisions that affect their child’s health. The thought is that knowledge enables: if mothers know what is best for children, they are better placed to secure it.

This thought can be challenged. While knowing what is best, and what is bad, for children, can help parents, it can only do so if what is best is within their power to secure. The costs of adherence may be prohibitive. Guidelines may advocate an unaffordable or inaccessible diet; other commitments may compete for time and energy; guideline adherence may provoke intrafamilial or intracultural conflict; co-parents may prevent adherence; social considerations (such as social disapproval of breast-feeding) or past history may increase the difficulty of adherence, to the point of effective impossibility.

It could be argued that the non-compulsory nature of guidelines offers sufficient recognition of legitimate obstacles to universal adherence to

guidelines. But guidelines also effectively set best practice standards. Nonadherence can stigmatize, potentially increasing inequalities when ability to adhere varies across social and economic groups (Goldberg 2012). If adherence to guidelines is not a straightforward matter of “parental choice” and child health is a goal worth pursuing, a social commitment beyond dissemination of recommendations may be required.

Industry Influence and the Integrity of Guidelines

The potency of child nutrition guidelines derives from their grounding in scientific evidence. The idea is that while parents have their own beliefs about what is best for their children, these beliefs are based on unreliable sources such as subjective assessments and inherited wisdom and may not be borne out by well-constructed, objective testing. Determining what is good for children requires more than guesswork; guidelines offer recommendations grounded in more reliable evidence than that standardly available to parents through experience, reasoning, and domestic experiments alone. Guidelines prepared for parental use are largely stripped of the scientific evidence base that renders them so influential. Parents are asked to trust in the integrity of the research underwriting them and the organizations preparing them.

The professed objectivity of guidelines and the implicit claim that their purpose is to assist parents to make the best possible nutritional decisions for their children are crucial components of their integrity. The involvement of vested interest groups, such as food manufacturers, would limit their trustworthiness: the possibility that the interests of these groups influenced the guidelines could not be discounted.

Links between industrial interests and nutrition guidelines have been documented. Some advisory organizations (such as the Academy of Nutrition and Dietetics) receive funding from industry (Nestle 2001). Industry lobbies committees and government agencies that prepare and issue guidelines (Nestle 2002). Furthermore, much of the research that guidelines draw upon receives

industry funding. Several studies have shown a link between research findings and funding (Lesser et al. 2007). Commercial attempts to influence child nutrition advice are not new: the new infant food companies courted dieticians' favor in the 1920s (Bentley 2005). Industrial influences compromise the perception of child nutrition guidelines as trustworthy and worthy of parental attention.

Summary

While parental duties with respect to child nutrition guidelines are disputed, they provide a measure by which mothers, as primary carers, can be evaluated, both by themselves and by others. This raises ethical questions about guidelines' suitability as measures of maternal success. In particular, the support that mothers receive to adhere to guidelines and the trustworthiness of guidelines are matters that require attention.

Introduction

Chinese agriculture is one of the oldest agricultural systems and one of the most influential, having contributed cultivars, techniques, and land management systems to neighboring peoples. Chinese agriculturalists have proven incredibly resilient. Adopting foreign cultivars and technology, such as wheat, the plow, and tea, they modified and expanded existing methodologies to transform an extensive, dryland agriculture into a multifaceted agricultural system including wet- and dryland crops, tree plantations, floating fields, and inland aquaculture. In doing so, Chinese farmers, historical and contemporary, have also had to grapple with significant ethical, social, and environment challenges. Long-term erosion, siltation, and flooding have been compounded, since the beginning of the twentieth century, by the social, economic, and environmental aspects of industrialization, intensified rural poverty, and the relative weakness of local administration. Today the ethical relevance of Chinese agriculture reflects a highly populated but changing rural-industrial society and is informed by technical, political, environmental, and social concerns associated with cultivation, including issues of land ownership and tenure, shifting

agrarian policies, environmental degradation, and labor out-migration and gender inequalities, among other issues.

Chinese Agriculture: An Historical Overview

Chinese agriculture began around the seventh millennium BCE in what is now northern China. Utilizing loess soils and mineral-rich windblown and glacial deposits, early farmers cultivated millet, wheat, barley, and soybeans (Ho 1969). In this phase, Chinese farmers faced important practical and environmental limitations. First and foremost, farmers struggled to retain soil water content, sometimes cultivating in shallow, man-made pits to preserve moisture. Second, staying warm during cold winters, coupled with gradual population growth, meant increasing consumption of forest resources. The results were land clearance, deforestation, and erosion. The region's rich soil thereby slipped into the Yellow River leading to rising water levels within the riverbed. This in turn required expensive, large-scale intervention in the forms of dredging and enlarged, reinforced embankments.

During the Han dynasty (206 BCE–220 CE), many of the major themes and crises of Chinese agriculture and ecology emerged: land agglomeration and the crisis of land access, the question of acceptable tax levels, flood damage and the necessity of government intervention, regional food scarcity requiring substantial infrastructure for distribution of food aid, farmer poverty, and agrarian protest. In these instances, the government was forced to reduce and sometimes suspend taxes while at the same time open granaries, issue loans, or provide seed, tools, and funds. In extreme instances, government land was loaned to farmers for cultivation (Hsu 1980).

With the building of the Grand Canal, a man-made waterway connecting the Yangzi and Yellow river valleys, during the Sui (589–618 CE) and Tang (618–908 CE) dynasties, the Chinese state successfully connected northern and southern Chinese agricultural zones. In doing so, the dryland dominated north and wetland dominated

south could exchange their products more readily. This enabled the collection of government tax grain as well as allowed for greater levels of market exchange. The Grand Canal should not be understated. Through it, the state could facilitate grain transfers, generally shifting southern rice surpluses toward northern grain scarcity.

Tang dynasty territorial expansion incorporated a greater swath of agricultural lands in the south, allowing migration and the enlargement of extensive agricultural methods. Initially, draft animal use increased, as did that of plows and harnesses. New seed drills were introduced which permitted the sowing of seeds simultaneously with an application of dung. Animal and human manure had become commodities by this time. Under this extensive agricultural regime, farmers multi-cropped, harvesting three crops in 2 years. They constructed framed or floating fields, mounds of earth suspended over wooden frames and mounted within rivers and lakes, which allowed for greater food production without adding season-long labor requirements. To facilitate the development of southern lands, local elites financed and maintained drainage and irrigation projects. The state, in an effort to reform agriculture, provided loans at lower rates of interest and replaced *corvée* with tax payment. The state attempted to rectify tax rolls to increase tax revenues but did not address land centralization and tenure. Although tax rates remained low, somewhere around 10%, tenants continued to pay 50% of their yields in rent, even more if they rented oxen and plows (Chao 1986).

During the following dynasty, the Song (960–1279 CE), the introduction of a new rice variety, Champa rice, reconfigured grain availability by drastically expanding China's rice production. Champa rice is known for being a drought- and flood-tolerant, insect- and blight-resistant strain which grows well on marginal soils. Because of its ability to grow on dry- or wetland, as well as its maturation in 100 days, roughly half the time needed for short and medium grain rice varieties, Champa rice made a significant contribution in alleviating famine and scarcity (Ho 1956).

Outside of grain production, Champa rice contributed to Chinese agriculture by emphasizing the importance of grain selection. Agriculturalists increasingly sought to find, and produce, varieties which matured in shorter periods, or which possessed specific traits. Farmers thereby produced or discovered in the eleventh and twelfth centuries varieties which matured in as little as 60 days. These varieties had lower yields but performed well on marginal soils enabling farmers to expand cultivable acreage. By the eighteenth century, there were 3525 documented rice varieties (Deng 1993).

In the Yuan (1279–1368 CE) and Ming (1368–1644 CE) dynasties, techniques for digging ponds improved, increasing the supply of water and land productivity. Better pond technology facilitated double cropping of wet- and dryland crops through improved water management. At the same time, in other parts of China, the adoption of more efficient crop rotations corresponded with a gradual decrease in farm sizes. The preference of landlords to divide large land holdings into plots workable by family units reconfigured the countryside into small fields rather than large tracts. Small fields, farmed intensively, discouraged animal-powered farm equipment and rewarded labor investment (Elvin 1982).

The application of labor-intensive agricultural methods, steady rates of land reclamation, the gradual improvement of agricultural implements and techniques, the importation of New World crops, and the continuing spread of best-practice agriculture collectively continued to fuel the growth of population and the economy. China's population had been around 100 million in the mid-seventeenth century. Around 1900, it neared 400 million. The quadrupling of population in a 250-year period was enabled on the one hand by a doubling in rice production between 1000 CE and 1850 CE and on the other by the introduction and dissemination of crops such as maize, sweet potato, and peanuts. Where rice accounted for 70% of China's national food output in the early seventeenth century, in the 1930s it was 36%. American food plants by then accounted for 20% of China's gross output (Ho 1959).

The cultivation of New World crops was in complement, rather than in competition, with China's dominant grains. Because sweet potato

and maize grew on soils less ideal for rice, wheat, or millet and could be cultivated on sloping lands where terracing was uneconomical, these crops allowed for an expansion in cultivated acreage and food supply without decreasing other grain production. However, the cultivation of these alternative soils, with the goal of short-term profits, facilitated practices which can best be described as deficit farming. At first farmers and landlords negotiated leases for lands which had not been in demand, leaving landlords feeling they were getting something for nothing. Cultivators then cleared and farmed the land without concern for soil preservation; the remaining soil was then susceptible to erosion. Over time, these practices contributed to China's agricultural expansion, population increase, and environmental degradation, especially in the mountains and along their connected waterways (Averill 1983).

Chinese Agriculture: Today

The commune system (1958–1978), through which farms and farmers were collectivized, ended through a series of reforms in the late 1970s and early 1980s. Under these reforms, China has experienced renewed agricultural growth rivaling advanced industrial economies. From the late 1970s to today, Chinese agriculture has seen an exponential rise in terms of the quantity and value of its goods. Yet while agriculture was a leading sector during reform, today it is increasingly marginalized. Moreover, it continues to face challenges of historical origin. Farmers retain land holdings too small to enable them to access the financial resources of credit and insurance markets. Without these, agriculturalists do not have the funds needed to improve their agricultural productivity (Song and Chen 2006). Chinese farmers are also threatened by the weakness of their legal rights to property. Because of ambiguities pertaining to land ownership and land tenure following the end of the commune system, farmers have been unable to assert, directly or through rural collectives, the rights of landowners. Rights of land tenure, the ability to buy,

sell, and profit from one's land, are not effectively outlined. The result is that, since the 1990s, there is a growing trend toward landlessness resulting from the encroachment of government eminent domain, private land enclosure, and land sales, as conducted by local officials (Hong 2006).

Agrarian Reform and WTO Membership

Under the commune system, local leaders decided what was cultivated. Farmers, on the other hand, possessed autonomy over crop selection generally only in regard to small plots near their homes. Local leaders made their decisions based upon plans given to them by higher-level officials. According to these plans, rural leaders were required to meet specific quotas in specific commodities. This system intended to create agricultural surpluses which could be shifted throughout the country, especially to areas of need, while keeping agricultural commodity prices low and facilitating industrial transition (Lohmar et al. 2009). However, such organization and state policy, without strong oversight, created a potential for overreporting which contributed to one of the largest famines of the twentieth century under the Great Leap Forward (Perkins 1991).

In 1978, a series of national reforms began which included significant alterations to Chinese agriculture. Under the Household Responsibility System, villages allocated collectively owned land to households through leases. In this system, farmers paid quotas of designated crops and in turn received fixed payments. Farmers were permitted to determine which crops to plant after allocating sufficient space to the crops demanded in payment of the lease. This enabled farmers to cash crop, focus on livestock, and sell surpluses directly to the market. The result was an initial step in reinvigorating the rural economy, as it directly resuscitated rural markets. Farmers benefited from this transition, and in response to early success, land and labor practices shifted to meet market demands. The overarching result was growth in farm family incomes, increases in cash crop and livestock production, new demands for marketing, and a gradual escalation in

nonagricultural income among rural households (Lohmar et al. 2009).

With the integration of the Chinese economy into the World Trade Organization (WTO) in 2001, state-owned trading enterprise dominance over agricultural products eased through lowering tariffs and trade barriers on agricultural products. At the same time, China's inclusion in the WTO came with member-approved subsidies. China originally sought a subsidy equivalent to 10% of the value of national agricultural production. However, WTO members, in line with the restriction for industrialized countries, wanted China's subsidy to remain at 5%. The approved rate rests at eight and a half percent, a figure which reflects the government's overall ability to intervene in the market (Dang 2006; Lu 2006).

WTO membership has encouraged significant alterations in agrarian state policy as well as in production. The government's tenth Five-Year Plan (2001–2005) emphasized that agriculture should be given priority in national economic development to ensure sustained and steady growth in farmer income. Starting in 2003, the government gradually began to reduce taxes on special agricultural products. In March 2004, a plan was announced to gradually remove taxes on all agricultural products. The removal of taxes on farmers for their agricultural commodities indicates a profound shift in production and state view. It reflects the necessity of state support to maintain a balance between farmer income and consumer prices. It also conveys the decreasing importance of agricultural production in terms of gross domestic product. That China can now afford to allow agriculture to go untaxed indicates a new stage in China's agricultural history. Yet even with the reduction of state taxes on agricultural production, farmers are not tax free. Local fees and levies remain in place. They vary by locale, as they remain at the discretion of local officials. Such fees are intended to finance medical care, schools, town- and village-level administration, as well as public facilities. Even with the reduction and removal of state taxes on agricultural production, local dues and local fees remain the larger concern as they can become a greater burden (Lu 2006).

Production, Producers, and Agricultural Improvement

Since reform, Chinese agriculture has experienced nearly three decades of increasing yields. In 2005, agriculture accounted for roughly 12.5% of China's annual GDP. Although this figure is small, it reflects a 336% increase in output since 1978 (Dang 2006). In terms of grain production (rice, wheat, and maize), 247 million metric tons of grain were produced in 1978. By 2008 the figure was 470 million metric tons. This increase reflects intensive land-use cultivation and has occurred without substantial mechanization. Especially notable growth has been occurring in maize production, which is utilized in China's livestock and industrial sectors. Growth has not been even across all agricultural sectors. Livestock and fishery production had increased substantially, from 15% and 1% of overall agricultural output in 1978 to 33.7% and 10.2% in 2005. These changes reflect the growing availability of animal proteins, particularly pork and eggs, at the cost of grain production. Today, China is the world's largest rice-producing country and is a net exporter of rice. It is also a net exporter of vegetables, fruits, and aquatic products. In most years, China is a net importer of wheat and soybeans as well as cotton, palm, and soybean oils (Dang 2006; Lohmar et al. 2009; Sonntag et al. 2005).

According to the 2007 agricultural census, there were 200 million farm households on an estimated 122 million hectares (494 million acres), averaging 1.5 acres per household. Reflecting the land tenure of the Imperial Period, these small holdings remain divided into small plots unevenly dispersed. Intensive practices, high levels of fertilizer application, double- or triple-cropped fields, and extensive irrigation characterize these farms. On this scale, Chinese agriculture is able to make use of capital-intensive chemical inputs, such as fertilizers, pesticides, and herbicides, but mechanization remains limited. As land and water limitations increasingly make themselves apparent, it is unclear whether production can continue to increase within the current structures of land holding and family labor practices (Lohmar et al. 2009).

In 2005, 745 million or more than half of China's 1.3 billion people were living in rural areas. Two-thirds were employed in agriculture, animal husbandry, and fishing (Dang 2006). In terms of rural labor, scholars note two trends which indicate significant social and cultural challenges: rural out-migration and gender inequalities. Rising urban-rural income disparity is a leading factor behind emigration. Reduced accessibility to education, urban-biased investment, and insufficient rural credit contribute by intensifying an urban-rural divide, which remains in cities' favor (Lu 2006). There is also a perceivable male-female wage gap. In terms of work itself, women are being left to tend fields, are given inferior access to off-farm employment, and earn less for on-farm work (Rozelle et al. 2006). Although China has one of the highest female labor force participation rates in the world, with about 84% of women (ages 15–60) in the labor force, and women comprise about 45% of the entire labor force, women tend to work at lower levels. Some scholars argue that discrimination against women has increased in the reform period in terms of recruitment, layoffs, and required early retirement. Others are more positive, seeing greater inclusion of women in labor and greater opportunities post-reform (MacPhail and Dong 2006).

Potentially related to changing labor availability, several trends are emerging in land use within the current system. Cropped acreage is decreasing while land assigned to pasture and grassland is increasing. A growing demand for meat is in part responsible, as the price of animal products has increased correspondingly (Dang 2006). Yet the requirements of animal husbandry are also a factor. Livestock management requires less labor than intensive grain production, allowing farm families to diversify their approach to the developing market economy.

In terms of state support, the decreasing value of agriculture to overall national wealth has put pressure on research and development as well as extension services, the local, regional, and national offices that research and disseminate information intended to improve agricultural production. Increasing funding to the extension service has grown progressively difficult to

rationalize. In part, there are structural reasons underlying this funding problem. The extension service remains overstaffed with little coordination between the central and substations, allowing for redundancy in research. Many employees spend only a fraction of their time on extension work, instead pursuing topics of little interest to farmers. For these reasons, recent changes to the extension service have made raising funds to support agricultural research institutes the responsibility of the institutes themselves. The matter is further complicated because of a lack of private institutes and private funding. Because extension services are a public endeavor, their status is central to discussions of ongoing agricultural improvement (Sonntag et al. 2005).

Connected to the issue of the extension service is that of farmer associations. As of 1995 there were around 100,000 farmer associations yet participation was quite low. Even with government initiatives to promote them, especially through a revision in 2002 to the Agricultural Law which provided a legal basis for their development and sanctioned them as legitimate providers of services to members, current estimates place 2–3% of households as participating. This can be explained through their location. Despite the high number of active societies, only 7% of villages have functioning associations, and many are congregated in regions which specialize on high-value crops and livestock (Sonntag et al. 2005). Thus what these figures indicate is a potential for infrastructural development. Farmer association and extension work, if extended to more villages and farmers, may facilitate future gains.

Summary

Associated with millennia of agricultural production, but especially the previous three decades of industrialization, specific environmental challenges have developed in China. Today Chinese agriculture approaches the upper limit of its ability to supply greater quantities of food and faces an assortment of grassland degradation, soil erosion and nutrient loss, atmospheric contamination, air and water pollution, and solid waste disposal

issues. As China's population continues to rise, increased pressure will be placed on the reclamation of marginal soils, furthering these processes and outcomes while intensifying trends toward salinization and desertification. Addressing these challenges will require significant alterations and reforms to existing policies and practices. Many scholars agree that comprehensive land reform is necessary, to emphasize farmer tenure, to declare firm property lines, to allocate water access, and to institute overall water safety and control mechanisms. To conserve soil and prevent erosion, recommendations include the wide-scale adoption of hedgerows into annual and perennial cropping systems, the utilization of rotational grazing, and diversified crop rotations as well as conservation tillage systems, including the conversion of fragile land to grassland or forest. To lower water and soil contamination, fertilizer and pesticide applications should be reduced through pest management strategies and optimized fertilizer applications. Improvements in forest management and replanting programs, and continuing reform of the extension service, require increased support to strengthen their services to farmers throughout China rather than specific regions (Dang 2006; Lohmar et al. 2009; Sonntag et al. 2005; Qu and Li 1994).

A survey of Chinese agriculture and its history reveals a narrative of farmers and farming which has successfully adapted to a variety of natural and human-centered challenges, supplying its own people, its region, and the world with highly valued and essential agricultural commodities. While there are many things to learn about the interactions between farming and the environment, Chinese agriculture poses potential lessons for contemporary farming practices. Perhaps the greatest are the value of adaptation and the latent benefits of labor-intensive practices. These appear to be integral parts of what very well may be an alternative model of agricultural improvement.

Chocolate: Ethical Dimensions

Craig K. Harris
Department of Sociology, Michigan State
University, East Lansing, MI, USA

Introduction

All you need is love. But a little chocolate now and then doesn't hurt.
Lucy Van Pelt

Like many human foods that require some processing, it is hard to know what was the mental process that led some Native Americans in what is now called Central America to convert the seeds inside a cacao pod to a desirable drink some 3500 years ago. Somehow it happened, and chocolate became a thread that can be followed through the rise and fall of empires, the expansion and decline of corporations, and the shifts in dominant food regimes from nation-states to corporate producers to food activists. Like many desirable substances, chocolate has been the focus of ethical and moral questions for at least the past millennium. At different points in time and at different places, chocolate has implicated all of the ethical issues of justice and rights, autonomy and consent, care and harm, and sovereignty and egalitarianism. This entry will provide an overview of the various ethical issues that over time have been implicated in the production and exchange and consumption of chocolate.

In order to establish a foundation so that the subsequent sections will be more comprehensible, the first section will provide a brief background of the biophysical and social processes that have combined over time to create the chocolate value system. The second section will describe the ethical issues that are implicated in the social relationships between the production and the consumption of chocolate. While the third section describes ethical aspects of the social relations of production including manufacturing, the fourth section outlines ethical aspects of the ecological relations of production. Ethical issues in the social and economic relations of exchange are the topic of the fifth section, while ethical dimensions of the modes of consumption are the focus of the sixth section. After a brief discussion of appropriation and substitution in the seventh section, the eighth section concludes the entry with a discussion of ethical activism along the value chain.

Background

Well, folks, it looks like we're up chocolate creek without a popsicle stick.
The Gingerbread Man

Chocolate comes from the small tropical tree *Theobroma cacao* L. of which there are three varieties – Criollo, Forastero, and Trinitario; “theobroma” comes from the Greek word for “food of the gods,” and “cacao” comes from the name for the plant (“kakaw” or “kagaw” or “cacahuatl”) in several Mesoamerican languages. The fruit of the tree is a pod containing a sweet pulp surrounding 30–50 seeds or beans. It was domesticated in the Amazonian basin of north-eastern Peru, probably accidentally and probably for the pulp surrounding the seed that was either consumed directly or fermented (Clement et al. 2010).

The pods are harvested during a large portion or all of the year manually using a curved knife on a long pole. The pods are opened, and the cocoa seeds and pulp are removed and kept in piles for several days, during which the pulp ferments and runs off. Next the wet beans are fermented for several days and then dried for several more

days, either in the sun or with artificial heat, after which the beans are polished with dry clay and shipped to one of the countries where chocolate is produced (Federation of Cocoa Commerce [n.d.](#)).

In a factory the beans are roasted, cracked, and deshelled to produce the small pieces called nibs, which are then ground into a thick paste (“chocolate liquor” or “cocoa paste”). The process splits into two tracks at this point. First, the liquor can be separated into cocoa powder and cocoa butter. Second, sugar and cocoa butter can be added to the liquor; the mixture is then refined, conched, and tempered to make chocolate.

Currently chocolate is used as an ingredient in industrial food manufacturing, for home cooking, and for ready-to-eat products. For the first 25 years of the Hershey Company, its products (powdered cocoa, chocolate syrup, chocolate chips) were solely for industrial consumption. Whereas the National Cookbook of 1856 in Philadelphia uses chocolate only to make a hot drink, in 1861 in England Mrs. Beeton’s Book of Household Management included a recipe for chocolate soufflé, and the Century Cookbook of 1899 in New York uses chocolate to make puddings, fillings and frostings, as well as hot drinks.

In 1842, Whitman’s was the first chocolate candy company in the USA. During the last 5 years of the nineteenth century, the Hershey Company was the first firm in the USA to develop milk chocolate, which was sold first in a milk chocolate bar and then as the iconic Hershey Kiss in 1907. In 1923 after 3 years of research, the Mars Company began selling the Milky Way candy bar. Nestle entered the chocolate sector with the acquisition of Peter, Cailler, Kohler Swiss Chocolate Company in 1925.

Currently cocoa beans are produced commercially in more than 20 tropical countries, with Cote d’Ivoire, Indonesia, and Ghana accounting for approximately two-thirds of total production volume and value (FAO [2013](#)). Currently most beans are exported to firms in the North to be roasted and ground; two of the top three grinders globally, Cargill and ADM, are commodity traders; only one, Barry Callebaut, is a chocolate firm. Wikipedia currently lists 59 identified companies that process ground cocoa into chocolate,

among which Cadbury (as of February 2010 part of Mondelez International), Barry Callebaut, Hershey, Lindt, Mars, and Nestle are the largest. Thus cocoa beans go from farmers to small traders to wholesalers to exporters, or from farmers’ cooperatives to the exporters, and thence to the grinders. The processed chocolate then goes to food manufacturers, including some who make ready-to-eat chocolate items, and most of the processors also produce chocolate items for retail trade. While the cocoa/chocolate value system is dominated by a few large firms that both process cocoa beans and manufacture ready-to-eat items, there does not appear to be any cartel controlling production and trade. None of the major companies appears to have vertically integrated either upstream into farm production or downstream into retail sales.

The Social Relationships Linking Production and Consumption

It’s everybody’s non-pollutionary, anti-institutionary, pro-confectionery factory of fun!
Willy Wonka and the Chocolate Factory

For almost all of its existence, chocolate has been implicated in imperial relations, beginning with Mesoamerican empires and then subsequently with European empires and neo-imperialist structures. As noted in the previous section, the tree was first domesticated in northeastern Peru and then spread northward into Central America. The earliest remnants of human consumption date from about 3500 years before the present time and were found in sites in what is now Honduras associated with Paleo-Indian cultures during the Archaic, pre-Olmec period. These remnants indicate that the technique of toasting and grinding the seeds and mixing the powder with the pulp and hot water and whipping the liquid into a frothy drink had been developed. This and subsequent archeological findings suggest that chocolate was always consumed as a beverage.

After the Olmec culture, the Mayans used chocolate for ceremonial purposes; there is some evidence that its consumption may have been restricted to the religious and political upper

class. Finally, for the Aztecs, chocolate was associated with Xochiquetzal, the goddess of fertility. (Ixcacao was the original Mayan goddess of fertility, but was supplanted by Ix Chel; the Aztecs keep the connection between fertility and chocolate, but change the name of the goddess to Xochiquetzal.) Cacao was produced in various parts of the empire and transported to the imperial centers; in some cases the tribute required from other areas of the empire was paid in cacao. Chocolate was viewed as a luxury good throughout the empire.

The first record of the dry mixture of ground cacao seeds and cacao pulp being shipped to Europe is from 1585, over 60 years after Cortes arrived in Mexico. Initially units of the Spanish army enslaved native Mesoamericans to produce cacao for export; it was marketed as an expensive luxury good. Subsequently Spanish landholders began importing slaves from Africa to grow cacao on plantations. After the countries of Latin America won their independence from Spain and Portugal in the early 1800s, the *forastero* variety of *Theobroma cacao* was taken from the area of its origin in western Amazonia to West Africa, where Ghana and Cote d'Ivoire are currently two of the three main producing countries in the world (Ryan 2011). While today this translocation of a valuable species might be regarded as a violation of biosecurity and food sovereignty, it was a common practice among the imperial powers in the 1800s and 1900s (Hecht and Cockburn 1991).

The popularity and price of chocolate led firms to develop new techniques for processing the cacao. In the 1700s it was discovered that the cocoa butter could be squeezed out of the cacao, leaving a hard durable chocolate, and in the 1800s solid chocolate was being produced in many European countries. In 1879 Rodolphe Lindt invented the conching process in which the chocolate paste is repeatedly spread over a surface and then scraped back off the surface continually for many hours to produce a softer chocolate with a less acidic, mild, rich taste.

During the 1800s and 1900s, the chocolate industry proceeded upon somewhat parallel tracks in Europe and North America, with ethical issues perceived to some extent on both sides of the Atlantic. In 1879 the Cadbury Brothers

established the town of Bourneville and located their manufacturing operations there. As noted in the previous section, the development of milk chocolate by Milton Hershey at the end of the nineteenth century led the company to shift its emphasis from goods for industrial food production to consumer goods. Although writers at the time saw ethical issues with company towns (the compound exploitation of the workers through low wages, poor working conditions, environmental pollution, high rents, and high prices at the company store and the pervasive discipline of the workers through a company police force and a company supported faith-based organization; cf. Porteous 1970), Hershey decided to build a new town in rural southeastern Pennsylvania proximate to the Chesapeake and Delaware Bays where the imported cacao beans and sugar would arrive (Craft 2009). Before World War I Hershey relied on beet sugar from Europe, but the disruption caused by the war led the firm to build a sugar plantation and production facilities in Cuba (<http://www.thehersheycompany.com/about-hershey/our-story/hersheys-history.aspx>). Again although many writers today would emphasize the ethical issues of land control and food sovereignty inherent in such a venture, it was a common practice by industrial firms at the time (Hecht and Cockburn 1991).

Finally, this section considers the ethical aspects of the organization of the chocolate industry. One of the ways in which developing countries with high reliance on exported commodities try to secure a fair price for their commodities is by gaining countervailing power in the international market against the large-scale buyers of the commodity through forming marketing boards at the national level and a cartel among the marketing nations. Most of the marketing countries established marketing boards after independence in the 1950s and 1960s, and like many commodities, an effort was made to form a cartel of cacao-exporting countries. Although negotiations began in 1963, it was not until 1972 that an agreement was reached under the auspices of the United Nations Conference on Trade and Development (UNCTAD) establishing a system of buffer stocks and export quotas (LeClair 2000, p. 64). Neither this agreement nor three subsequent agreements

were successful in stabilizing the market price at the level desired by the exporting countries. The nation with the largest production, Cote d'Ivoire, refused to participate, and new producers such as Malaysia entered the market in the 1980s. The marketing boards themselves were victims of the World Bank and International Monetary Fund policies of structural adjustment in the 1980s and 1990s. As a result of the failure of the cartel and the forced abolition of the marketing boards, the real price of cacao beans at New York fell from \$1,613.70 per metric tonne in 1974 to \$589.75 in 1996.

While the cocoa-exporting countries have not been successful in using their market concentration to obtain better prices from processors, the processors have perhaps been more successful in using their market power to obtain higher prices from consumers. The chocolate industry is highly diffuse globally; most of the large firms are active in many countries. Worldwide, the five largest firms in the industry (Ferrero, Hershey, Mars, Mondelez (Mondelez International is the name of the US-based multinational corporation comprising what were formerly the chocolate and confectionery holdings of the Kraft Corporation, including Cadbury and Toblerone.), Nestle) control slightly more than half of the market (IBISWorld 2013). As a result, despite the distressed global economy and rising sugar and cocoa prices, profit as a share of total revenue is expected to rise to 8.6% for the industry as a whole. Much of the recent increase in concentration has come through mergers and acquisitions (e.g., Hershey bought Reese, Mars bought Wrigley) that have impacts on employment and community well-being that raise ethical issues. One way in which firms in Europe and the USA have been able to use their political power is to obtain favorable government policies on sugar production and importation (USDA ERS 2012).

The Social Relations of Production and Manufacturing

The previous two sections have noted that during much of its history, various aspects of the cacao

production system have been ethically problematic. However, during the past three decades, much of the ethical focus has been on the social and economic relations of production and manufacturing and of marketing and exchange.

With the exception of Brazil and Ecuador, cacao is grown on the farms of smallholders having generally between 1 and 3 acres (Franzen and Mulder 2007); in Brazil the average cocoa farm is 20 ha. Despite the relatively small scale of African and Asian cocoa farms and despite the fact that cacao pods are harvested year-round, a large amount of labor is required for the harvesting and on-farm processing (dehusking and fermentation). For example, the average farm in Cote d'Ivoire produces approximately 4 kg of intermediate product per day (ICCO n.d.). As noted in the previous section, cocoa farmers have had to deal with gradually falling prices for their crop, and because labor is their main cost, they have had to reduce the cost of labor as much as possible. To do this they have chosen to rely on child labor and to maintain those children and other laborers in conditions that have been labeled as slavery. While the ethical issues with slavery may be clear to all, the International Labor Organization (2004) indicates that the forms of child labor that raise the most ethical issues include cases where children working in cocoa are not enrolled in school, where work makes them leave school prematurely, or where they have to combine school attendance with long hours and/or heavy work that interferes with their learning.

Berlan (2013) argues that labor in cocoa production needs to be analyzed using a broad understanding of the degrees and forms of labor coercion rather than a simple dichotomization of free and unfree labor. Her analysis of her fieldwork in Ghana shows that the range of choices children have is significantly constrained by their family situation, so that while they may not be working against their will, their ability to exercise agency was very limited. She also argues that it is important to distinguish between local labor and trafficked labor and to be very careful about the accuracy of information about the latter. While both child trafficking and children working in

hazardous activities are illegal, Berlan focuses on the latter, noting that the involvement of children in hazardous activities probably applies equally to local child workers and trafficked child workers. Berlan notes the difficulty of distinguishing between (acceptable) child work and (unacceptable) child labor. While the concepts of apprenticeship to learn a trade, and unpaid family labor, may be widely used, they do not clearly distinguish between child work and child labor.

Concerns about de facto slavery in cocoa production were not a new thing in the late twentieth century; in the middle and later 1800s articles in *The New York Times* expressed concern about the use of slaves in cocoa production in the Caribbean and Latin America. In the early 1900s, Cadbury shifted its sourcing from the Portuguese western African islands to what was then the Gold Coast Colony because of allegations that Portuguese growers in the islands were using slaves from the Portuguese colony of Angola on their cocoa plantations (Satre 2005). Shortly thereafter the topic pretty much disappears from the pages of *The New York Times* until the 1980s, where it continues sporadically up to the present time. A series of articles in the *Milwaukee Journal* (Raghavan and Chatterjee 2001) and a BBC broadcast also in 2001 increased attention to slavery in cocoa production (Wikipedia 2013). While Off (2006) documents the conditions of “enslavement” under which Malian boys work on cocoa farms in Cote d’Ivoire, Berlan (2013) did not find slave labor in the community she studied in Ghana. As noted above, Berlan (2013) argues that while de jure slave labor may be readily identifiable, de facto slave labor is much less clear and more nuanced.

The social and economic relations of production occur both in the cocoa fields and in the chocolate factories. Both in Western Europe and in the USA, labor in chocolate factories participated in the unionization movements of the late 1800s and early 1900s. Although an effort by the Congress of Industrial Organizations to organize the Hershey Chocolate Corporation workers against the paternalism of the company town ended in failure after the company broke a sit-down strike in 1937, the Bakery and Confectionery Workers’ International Union of America,

affiliated with the American Federation of Labor, was more successful in 1939.

Labor maintained an improving socioeconomic status until the rise of neoliberalism in the 1980s. During the past 30 years, mergers and acquisitions have resulted in decreasing employment in production facilities in North America and Europe. At the same time increasing globalization of marketing has led firms to open new plants in Latin America, Africa, and Asia. In 2002 some of the trustees of the Hershey Trust that owned the Hershey Chocolate Corporation voted to sell the corporation to the Wrigley Corporation; however the proposal provoked tremendous community and regional opposition, and the Pennsylvania attorney general was able to remove the trustees from office, so the sale did not take place. Most recently, the Hershey Corporation faced strong criticism for bringing foreign students to work on educational internships in its factories but then paying them very little to do line jobs that entailed no training or education.

The Ecological Relations of Production

The cocoa value chain involves not only social relations of production with other social actors but also ecological relations of production with elements and aspects of the biophysical environment. Although Morbey (1995) argues that cocoa is a crop that has the potential to protect the environment, most of the literature emphasizes the ways in which cocoa production extracts value from the biophysical environment in unsustainable, unregenerative ways and in doing so degrades the ecological functioning of the agroecosystem. Ekanade (1991, 1992) describes the ways in which and the extent to which cocoa production in Nigeria degrades the fertility and health of the soil and the health of the forest land cover. Not only have the biotic and edaphic components of the agroecosystem in the Nigerian Cocoa Belt been almost totally degraded, but in many areas of the belt, cocoa production is being abandoned.

In a life cycle assessment of cocoa grown in Ghana, Afrane and Ntiamoah (2011) found that

freshwater aquatic ecotoxicity was the most significant negative impact on the biophysical environment from pesticide use and that “the production and use of fertilizers and pesticides account for almost all the environmental burdens in the cocoa production stage.” Cocoa farming also contributes to rainforest and old growth forest deforestation (England 1993). By clearing land into these forests, farmers decrease the biodiversity and interactions between the organisms that naturally live in this area (Bentley et al. 2004). Many wildlife habitats are destroyed and the plant species diversity is drastically reduced (cited in http://en.wikipedia.org/wiki/Environmental_effects_of_cocoa_production). The extent of deforestation has increased as the production of cocoa has shifted from shade-grown to sun-grown techniques; sun-grown techniques are more productive per hectare, but produce a lower-quality cocoa. And as chocolate manufacturers have substituted palm kernel oil for cocoa butter, the deforestation caused by environmentally damaging palm oil production has been an issue (<http://www.foodnavigator.com/Product-Categories/Chocolate-and-confectionery-ingredients/ADM-Cocoa-UK-commits-to-100-segregated-certified-palm-oil-in-Europe>).

Ecological relations of production occur both with respect to productive activities on the farm and with respect to processing and manufacturing activities in factories. The literature did not identify any environmental issues with processing and manufacturing activities, perhaps because these take place largely in Europe and North America where environmental impacts from manufacturing are legally regulated.

The Social and Economic Relations of Exchange

Another one of the loci in the chocolate value system where ethical issues occur is in the linkages between sellers (suppliers) and buyers (intermediate and/or final consumers). These linkages occur between farm producers and middlepersons, between middlepersons and exporters, between exporters and processors,

between processors and manufacturers, between manufacturers and wholesale and retail distributors, and between retailers and final consumers.

Perhaps the greatest amount of attention concerning the ethics of chocolate has been paid to the equity of the exchange between farmers and first buyers. During the 1980s, alternative trading organizations gradually shifted the composition of their merchandise from handicrafts to agricultural goods – initially coffee and tea and subsequently cocoa and other foodstuffs (Wikipedia 2013). But to expand the market beyond the ATO’s own outlets, some way of communicating to the buyer the alternativeness of the merchandise was needed; to meet this need, fair trade labels were developed (Renard 2003). During the 1990s fair trade labeling organizations proliferated in Europe and North America, but in 2002 the Fairtrade Labeling Organization International (FLO) attempted to unify the multiple organizations under one process and one label. Although effective for about 10 years, within the past couple years, divisive conflict has occurred within the FLO.

In general, fair trade arrangements are negotiated directly with a growers’ cooperative, guarantee a minimum price that will cover production costs, and include both a long-term contract and community investment, all in order to avert environmentally degrading production practices, unremunerative economic transactions, and unethical labor practices (Khamis 2012). One exemplar, Divine Chocolate Ltd. was formed in 1997 as a joint venture between a Ghanaian cocoa growers’ cooperative, a fair trade supply chain management company, and a cosmetics retailer (Davies 2010); not only the cocoa but also the sugar in their chocolate is fair trade, and the company manufacturing their chocolate is fair trade compliant. As another example, after the addition of an emphasis on fair trade to its original organic identity, sales of Green and Black’s chocolate in the UK grew significantly. But, as Khamis (2012) points out, the increase in sales has been accompanied by a de-emphasis of the ecologically and socioeconomically ethical aspects of the chocolate, and the manufacturer has not made any effort to make ethical consumption more available to lower-income

consumers; while the chocolate value chain has been made equitable for some farmers, the value chain itself has not been transformed to rectify basic structural inequities.

While there were concerns that Green and Black's ethical approach might be diluted when the firm was acquired by Cadbury, in fact 4 years later Cadbury committed its main product line to fair trade, in effect tripling fair trade chocolate sales in the UK (Boyle 2009). This commitment appears to have endured through the acquisition of Cadbury by Kraft late in 2009 and the spin-off of Kraft's confectionery lines into Mondelez in 2012. Holmyard (2007) noted that many retailers were adding fair trade items to their own brand lines but also questioned the extent to which these additions were impacting the ethical issues to which fair trade is directed. In fact, many of the own-brand fair trade items were being supplied by the Divine Chocolate Company (formerly the Day Chocolate Company), but this led critics to question the ethical value of selling a fair trade item in a store that was not itself committed to the social, economic, and environmental principles of fair trade (Davies 2010). These questions were intensified when the Divine management proposed selling their products at Royal Dutch Shell stations and McDonald's outlets.

As noted above, the cocoa-exporting countries were never successful in forming a cartel to provide power in the international market for raw cocoa to countervail the oligopsonistic power (the ability to set prices significantly lower than those that would occur in a truly competitive market) of the cocoa processors. Although cocoa producers enjoyed a brief rise in prices in the mid-1970s, by 1982 prices had returned to their historical lows where they remained until 2008, illustrating the market power of the processors (<http://www.tradingeconomics.com/commodity/cocoa>). In addition, Khamis (2012) suggests that speculative buying on the cocoa futures markets leads to wide fluctuations in prices that destabilize the marketing arrangements of the producing countries. At the downstream end of the value chain, the large manufacturers were accused of using their

oligopolistic power to fix retail prices for their products in Canada in 2007 (Johnston 2013).

Finally, the social and economic relations of exchange concern the marketing of chocolate to final consumers. This will be discussed in greater detail in the next section, but here one particular ethical issue merits mention – the marketing of chocolate to children. Based on the premise that chocolate is an unhealthy product, Davies (2010) questions the ethical appropriateness of advertising chocolate directly to children, even if, as was the case with Divine products, the chocolate was ethically produced and was accompanied by educational material concerning the means and relations of production. In 2007, Mars was the first food company to voluntarily cease advertising to children younger than 12 years of age (<http://www.mars.com/global/about-mars/history.aspx>).

Modes of Consumption

What you see before you, my friend, is the result of a lifetime of chocolate.

Katharine Hepburn

In contrast to modes of production, which have ethical implications because of their impacts on the well-being of workers and the biophysical environment, modes of consumption refer to the ways in which the organization and performance of consumption have ethical implications because of their impacts on the well-being of all consumers and the biophysical environment. At the heart of the analysis of modes of consumption of chocolate is the question: what is the social meaning of chocolate? In brief, over its history chocolate has gone from being an elite luxury item to a treat affordable by middle class consumers, to an item of mass consumption, and finally back to an element of foodie aesthetics. Whereas 100 years ago Hershey was Fordist chocolate, a couple decades later Mars was Sloanist chocolate, and now Ghirardelli and Godiva are foodie chocolate (Medeiros 2000).

During its recent history, much of the contestation concerning chocolate has focused on its

health impacts. Articles in *The New York Times* 100 years ago claimed that eating chocolate was harmful to human health and chocolate was banned from US Army rations during World War I (*New York Times*, 15 December 1913, 29 December 1914). Over the years, chocolate has been implicated in acne, obesity, and diabetes. Perhaps to counter the negative discourse, in 1923 Mars introduced the Milky Way; the “milk” in the Milky Way was malted milk, then perhaps more than now seen as a healthful ingredient. More recently, scientific studies have supported the beneficial impacts of chocolate consumption on cognitive function, hypertension, and insulin resistance (Desideri et al. 2012). The debate about the positive and negative human health impacts of chocolate has been the focus of two recent major edited volumes (Paoletti et al. 2012; Watson et al. 2012); together the two books comprise 52 chapters that cover the relationships of chocolate to almost every aspect of human physical and mental health and well-being. Just to illustrate the tremendous richness and diversity of the debates, one chapter questions the relationship between chocolate and acne, and another argues that consumption of chocolate helps prevent diabetes. As further evidence of the complexity, the Hershey Company is currently facing a class action lawsuit for making an antioxidant health claim that was not approved by the US Food and Drug Administration (<http://www.confectionerynews.com/Manufacturers/District-court-will-not-dismiss-Hershey-antioxidant-labeling-suit>).

To a significant extent, the shift in the medical perspective on chocolate has been linked to a shift in the formulation of chocolate items. Concerns about the impacts of chocolate on acne, obesity, and diabetes were based on formulations of chocolate that included significant amounts of sugar and milk to balance the bitterness and acidity of the cocoa. The current emphasis on the health benefits of chocolate consumption is based on formulations of “dark chocolate” that are as much as 87% cocoa and thus have a higher prevalence of the beneficial flavanols (Gray 2012). At the same time, the increasing popularity of very dark chocolate has been linked to the upscaling of

chocolate consumption. Although Hershey had marketed a “Not So Sweet” bar in 1934, it was not popular and was discontinued in 1937 (<http://www.thehersheycompany.com/about-hershey/our-story/hersheys-history.aspx>). But by the 1980s, dark chocolate (70% and above) was portrayed in the pages of *The New York Times* as desired by more sophisticated, gourmet tastes. As Woerle (2012) notes, the desire to be consuming the elite quality chocolate becomes entwined with the wish to be consuming ethically produced chocolate.

Ultimately chocolate is, at least in part, what consumers want it to be. In the previous sections, the ethical dilemmas with chocolate being a sweet for children were noted. Chocolate has always been seen as an energy food; in the 1900s Hershey marketed chocolate tablets for energy, and more recently Mars introduced a chocolate energy bar. Currently however chocolate has yielded the energy mantle to specialized energy drinks, and it is those products that are dealing with the ethical issues associated with rapid, powerful, and enduring elevated human energy levels. Throughout its history there have been claims that chocolate has aphrodisiac effects (Afoakwa 2008), and Davies (2010) criticizes Divine Chocolate for participating in sexually themed Valentine’s Day competitions. One website urges men to think of chocolate as a sweet treat, an arousing flavor, and an alluring scent for seducing women (http://www.askmen.com/scent/scent_300/332b_seduce-her-with-chocolate.html). And finally, in contrast to the view of chocolate as a gourmet delicacy, chocolate is increasingly portrayed as convenient. Although pieces of chocolate covered with a hard shell had been developed in Europe and were issued to soldiers in the Spanish Civil War, their popularity was greatly increased when Mars began using the slogan “melts in your mouth, not in your hand” for its M&M products in 1954 (<http://en.wikipedia.org/wiki/M%26M%27s>). Both Mondelez (formerly Cadbury/Kraft) and Nestle have recently developed a “non-melting chocolate” to increase their sales in markets with hot climates (<http://www.foodnavigator.com/Product-Categories/Chocolate-and-confectionery-ingredients/Nestle-s-answer-to-non-melting-chocolate>).

Appropriation and Substitution

Life is like a box of chocolates. You never know what you're gonna get.
Mrs. Gump

In 1987 Goodman et al. proposed that industrial capitalism tends to restructure the agrifood system by appropriating non-capitalist production, by bringing processing and marketing functions into the ambit of the capitalist agrifood system, and then by substituting industrialized synthetic forms of those materials and processes for the traditional authentic originals. Hopefully the second section of this entry provided at least a rough sense of the ways in which artisanal chocolate was appropriated from artisanal producers first by the native Latin American empires and subsequently by the European colonial empire and then in the late 1800s appropriated from European and North American craftspeople by the emerging industrial confectionary firms. In this section then we turn briefly to a discussion of the ethical issues entailed in the tendency of industrial capitalism toward substitution.

Many nations have established standards of identity for cacao, chocolate liquor, and different intermediate and final chocolate products. In the USA, the Food and Drug Administration sets standards for the purity of cacao nibs, the percentage of cacao fat and dairy fat in chocolate liquor, and, for example, the percentages of chocolate liquor and milk solids and carbohydrate sweeteners in milk chocolate (<http://www.accessdata.fda.gov/scripts/cdrh/cfdocs/cfcfr/CFRSearch.cfm?fr=163.130>). Within the boundaries set by these standards, chocolate companies attempt to identify ways to produce products that will be acceptable to their customers at the lowest possible monetary cost, subject to other constraints, e.g., health. For example, “the historical uncertainty in the cocoa butter supply and the volatility in cocoa butter prices forced confectioners to seek other alternatives” such as palm kernel oil (Wang et al. 2010, p. 1137). And even though both the USA and the EU have policies on sugar that benefit confectionary companies, chocolate companies are substituting high-fructose corn syrup for sugar.

The question is whether these substitutions implicate an ethical issue. The companies conduct very sophisticated sensorial testing to determine whether a significant percentage of users will notice any organoleptic difference caused by the substitution. And the substituted ingredients are clearly listed on the label. So the substitution would seem to pass the ethical tests of transparency, aesthetics, and harmlessness, albeit not prior informed consent. Indeed the companies justify some of the reductions in fat content as efforts to reduce the calories in chocolate to improve its healthfulness. Perhaps the lingering ethical issue is the distribution of the net income attributable to the substitution between the company and the buyer.

When less expensive ingredients are substituted and the substitution is not included on the label, it is considered to be counterfeiting and fraud and thus a violation of generally accepting ethical norms (http://www.nytimes.com/2013/06/27/business/food-fraud-more-widespread-than-suspected.html?pagewanted=2%26_r=0). Less clear-cut may be the issue of artificial chocolate flavoring. Research and development in food chemistry has now produced an artificial chocolate flavor that is not readily distinguishable from cocoa or natural chocolate flavor in many uses. Currently US FDA regulations permit the product made with this artificial flavoring to be labeled “chocolate artificially flavored” and require that the list of ingredients include “artificial flavors” (<http://www.fda.gov/ICECI/ComplianceManuals/CompliancePolicyGuidanceManual/ucm074446.htm>). Also less clear-cut is the increased use in chocolate of what in the past were waste products from the chocolate production process. For example, Barry Callebaut has developed a process to grind cocoa shells into a powder fit for use as a cocoa replacer, fat bloom inhibitor, and ingredient in other foods (<http://www.confectionerynews.com/Ingredients/Cocoa-shell-powder-has-numerous-uses-in-chocolate-and-foods-says-Barry-Callebaut>). While the repurposing of what had been waste into a food ingredient may be an ecological improvement, it raises the question of the extent to which consumers should be publicly consulted about changes in the composition of a traditional and iconic food like chocolate.

Ethical Activism Along the Value Chain

Nobody knows the truffles I've seen.
George Lang

While preceding sections have considered the various ethical dimensions of chocolate, in this section the focus is on applied ethics – the various forms of social activism that have sought to give prominence to those ethical issues. As noted above, the development of fair trade marketing arrangements for cocoa began in the early 1990s, at least in part in response to falling cocoa prices on the world market and to a perception that earlier development efforts had led smallholders to become dependent on the production of one or more commodities for export. The fair trade movement sought both to develop suppliers whose relations of production and exchange could be accurately characterized as “fair” and to develop marketing arrangements where the “fairness” identity could be maintained and thus a price premium could be realized. In the late 1990s, various human rights, children’s rights, and labor rights groups in the USA began publicizing and campaigning against slavery and child labor in cocoa production along with other economic activities. Various international environmental groups (e.g., Rainforest Alliance) have publicized the ecological issues associated with full sun cocoa and unsustainable palm oil.

Although it is generally agreed that these activist efforts have had impacts, there is less agreement on the substance and extent of those impacts. As noted above, Berlan (2013) argues that in many cases the local understanding of children’s involvement in cocoa production is very different from northern and western understandings of “slavery” and “child labor.” She (Berlan 2008) also suggests that only a small percentage of the cocoa that is certified for fair trade is actually traded through fair trade channels. Nevertheless the activism has certainly stimulated a response, in at least some cases a significant response, from the corporations involved with chocolate. In 2012 Hershey announced that by 2020 it would use only fair trade certified cocoa and that it would accelerate its efforts to eliminate child labor in its

supply chain (https://en.wikipedia.org/wiki/The_Hershey_Company). ADM Cocoa UK has committed to 100% certified palm oil for its European operations, and Mars had committed to 100% sustainable supply of cocoa by 2020 and zero environmental impact by 2040 (<http://www.foodnavigator.com/Product-Categories/Chocolate-and-confectionery-ingredients/ADM-Cocoa-UK-commits-to-100-segregated-certified-palm-oil-in-Europe>; <http://www.mars.com/global/about-mars/history.aspx>). To avoid mandatory federal certification and labeling of chocolate as “slavery-free,” in 2001 the corporations engaged in the importation and production of chocolate committed to a voluntary protocol to end child labor by 2005; 10 years later the terms of the protocol had still not been fulfilled (<http://topdocumentaryfilms.com/dark-side-chocolate/>).

In some ways ethical activism concerning chocolate has been made easier by the fact that two occasions of peak chocolate consumption are Valentine’s Day and Halloween; it is easy to argue that candy given to children on Halloween should not have been made with child labor and the candy given to one’s romantic partner should not have been bought for an unfair price. But those morally principled stances themselves entail ethical issues. Berlan (2013) questions the appropriateness of using commercial transactions to impose northern and western understandings of children’s rights on other cultures and suggests that many of the corporations involved with the production and manufacturing of chocolate have done more than fair trade arrangements to improve the well-being of cocoa-producing communities. Indeed, for several years, the International Cocoa Organization has been urging its members to pay more attention to raising the income levels of poor cocoa farmers. In contrast to concerns about the inappropriate imposition of western standards, in 2007 “the Roundtable for a Sustainable Cocoa Economy (RSCE) met for the first time to start a dialogue of sustainability across the gamut of cocoa production – farmers, co-operatives, traders, exporters, processors, chocolate manufacturers, wholesalers, government representatives, NGOs, financial institutions and donor agencies.” (Khamis 2011).

Conclusion

La impericia al batirlo puede ocasionar de un chocolate de excelente calidad se convierta en detestable...

Como Agua Para Chocolate

This article has identified (1) some of the ethical issues entailed in the production and marketing of chocolate, (2) the various efforts to address those issues, and (3) ethical concerns about those activist efforts. Certainly some ethical issues that could have been covered have not. Perhaps most notable among these are the issues concerning gender and chocolate; in apology for their omission, I can only say that they are covered by Austin (2005) and Robertson (2009). With that apology, in conclusion I will briefly highlight four emerging issues concerning chocolate.

First, like all contemporary crops and agriculture, cocoa production will be significantly affected by anthropogenic climate change. Currently *Theobroma* species grow largely in the tropics spanning 20° on either side of the equator. The extent to which *Theobroma* will be able to thrive farther away from the equator will depend on the ways in which both temperature and precipitation regimes change in the subtropical regions (<http://thechronicle.com.gh/ghana%E2%80%99s-cocoa-production-to-decline-in-20-years/>).

Second, while cocoa production has been the proximate cause of significant environmental change, in the years ahead, it itself will be significantly affected by various forms of global environmental change. Already deforestation in Cote d'Ivoire is threatening both the human rights and the land rights of cocoa producers (<http://planetark.org/wen/69108>).

Third, the trade-off between shifting production to developing countries and decreasing employment in the North presents an ethical dilemma. On the one hand, developing countries rightfully expect to develop economically by doing themselves more of the processing of the raw commodities they produce. On the other hand, the well-being of whole communities in the North such as Hershey, Pennsylvania, depends on employment in chocolate processing and manufacturing.

For example, Barry Callebaut has opened its second factory in Mexico, costing \$48 million, to supply chocolate to Grupo Bimbo, the domestic market, and Central America (<http://www.foodnavigator-usa.com/Suppliers2/Barry-Callebaut-opens-48m-factory-in-Mexico>).

The final emerging ethical dimension of chocolate concerns local and artisanal production both in the North and in the South. While Hershey, Mondelez, and Mars dominate the chocolate candy shelves of the supermarkets, there are 15 small-scale chocolate makers in the USA, and all large- and medium-sized cities have at least one or two small-scale shops where intermediate chocolate is reformulated to a desired level of sweetness or bitterness and then made into various sorts of candy specialties. These artisans are using their craft and their creativity to produce chocolate items that participate in the ethic of local and regional alternative food systems.

How these artisanal producers will fare in the years ahead and how small-scale cacao growers in Africa will fare in the years ahead remain to be seen. Hopefully this entry has given the reader some reason to believe that as their fates unwind, at least some of the consumers and manufacturers and dealers in the chocolate value chain will be thinking about the ethical dimensions of their relationships with chocolate.

Introduction

The relationship between Christianity and vegetarianism is complex and long-standing. On the

one hand, vegetarianism has never been a significant part of Christian theology or practice, especially in the West, and most Christians today think of their dietary choices as nonethical decisions that are largely irrelevant to their faith. To the extent they address the issue at all, Christians typically defend meat consumption by noting that God gave humans “dominion” over the rest of creation (Gen 1:28), that he created humans but not animals in “his image” (Gen 1:27), and that humans have souls while animals do not. In other words, man is understood to be morally superior to the rest of creation in a way that gives him permission to eat nonhuman animals more or less as he chooses. Historically, this point of view has been supported by most Christian theologians and ethicists, including leading thinkers such as Augustine and Thomas Aquinas. For Augustine, eating animals is not sinful because God put them on earth for human use. “To refrain from the killing of animals,” he writes, “is the height of superstition” (Augustine 1966, p. 120). Influenced by both Augustine and Aristotle, Aquinas agrees that there is nothing wrong with eating animals, since they are man’s natural inferiors, owing to their lack of reason. The “order of nature,” he writes in several places, condones human consumption of animal flesh.

On the other hand, there is both biblical support and historical precedent for advocating vegetarianism on the basis of Christian ethics. While many passages in the Bible support meat eating, it also usually represents the use of animals for food as in some way problematic. Other passages are more favorable to vegetarian arguments. Some of Jesus’ first followers eschewed meat, and many later Christian groups such as the Carthusians, Benedictines, and various monastic communities had or continue to have vegetarian commitments. For most of Christian history, abstaining from meat has been an integral part of Lent and other ritual practices. Prominent Christians such as Tertullian, Origen, Marcian, St. Benedict, John Wesley, Albert Schweitzer, Leo Tolstoy, and Karl Barth defended vegetarianism. Several recent Christian authors make the same case. Typically, Christian vegetarians do not deny that eating meat in some circumstances is ethically justifiable, but they portray vegetarianism as an

obligation for those who have good alternatives to meat readily available to them.

While Christian arguments for vegetarianism often parallel secular ones, two commonalities are distinctive of Christian approaches. Methodologically, claims made within Christian ethics are biblically based in some way, either by relying on Old or New Testament passages directly or by drawing out the implications of scripturally grounded general ethical principles. Substantively, Christian perspectives are united by the claim that only a vegetarian lifestyle shows proper reverence and appreciation for the goodness of God and his creation. This point can be developed in different ways, and since different strands of Biblical evidence can be adduced in support of it, Christian ethics gives rise to a variety of arguments for vegetarianism.

Protological and Eschatological Arguments

One of the most common themes among Christian vegetarians is the protological assertion that vegetarianism represents God's original intent for his creation. God grants man "dominion" over the earth after proclaiming every creature in it to be good. Then he says, "See, I have given you every plant yielding seed that is upon the face of all the earth, and every tree with seed in its fruit; you shall have them for food" (Gen 1:29). After extending this command to nonhuman animals as well, God pronounces his vegetarian creation "very good" (Gen 1:31). Perhaps more than any other passages, these verses are used to claim a Biblical basis for vegetarianism. Christian vegetarians emphasize that man's "dominion" is not a license to tyrannize, and it does not justify unrestricted meat eating in the way commonly supposed. Rather, these passages show that humans are to be creation's stewards, with caretaker responsibilities towards what ultimately belongs to God.

The message of the Edenic picture soon becomes more ambivalent, however. After the Fall and the Flood, God explicitly permits meat eating as an apparent concession to human sinfulness. "Every moving thing that lives shall be food

for you; and just as I gave you the green plants, I give you everything" (Gen 9:3). God adds the caveat that humans "shall not eat flesh with its life, that is its blood" (Gen 9:4), a point reaffirmed in Lev 3:17, 17:14, Deut 12:23, and later by the Jerusalem Council (Acts 15:19–20). God also directs humans to kill animals and eat them. At the first Passover in Egypt, the Israelites are told to slaughter and eat lambs, an event Jews commemorate annually in the traditional Passover feast. God allows the eating of other animals at Lev 11, and he directs their sacrifice in Lev 16:3–19 and in other places as atonement for human sin.

While these points complicate the protological argument for vegetarianism, arguably they do not vitiate it entirely. God's permission to eat meat as a response to human weakness does not necessarily retract vegetarianism as a moral ideal. Moreover, at no time does God indicate that animals exist merely to gratify human desires. In its own way, the Noachide covenant that blood, the life force, must be drained from an animal's carcass before it is consumed reaffirms the value and sacredness of life. Compared to pagan religions in the ancient world, the Jewish worldview displays an unusual degree of respect for animals. Lastly, although animal sacrifice was part of Jewish religious practices, Christians generally believe that the need for it was forever put to an end by Christ's sacrifice on the cross. The author of the Letter to the Hebrews represents Jesus as saying that he has abolished sacrificial animal offerings to do God's will (Heb 10:1–14).

Eschatological or future-oriented arguments for vegetarianism also find support in the Old Testament. Isaiah includes the well-known prophecy that "the wolf shall live with the lamb," "the leopard shall lie down with the kid, and "the lion shall eat straw like the ox" (Isa 11:6–7). This vision of the "peaceable kingdom," as it is often called, refers to God's promise of a "new heavens and a new earth" free of pain, destruction, and violence (Isa 65:17). Along these lines, contemporary Christian vegetarians often argue that ending violence towards animals is necessary to bring about the Kingdom of God promised in the New Testament. While this Kingdom is sometimes interpreted as a state of affairs that will come about by divine intervention alone, most

contemporary scholars understand it as an already-initiated process in which humans are full and active participants (Webb 2001). The claim is thus that man's obligation to live in anticipation of the Kingdom requires foregoing meat so far as possible.

Asceticism

Many contemporary secular vegetarians are motivated primarily by a concern for personal health, and some Christian vegetarians have a similar focus. The thought is that since humans' bodies are gifts from God, they are obligated to take care of their health. Given the deleterious physical effects of meat eating, at least when consumed in large quantities, vegetarianism is seen as an acknowledgment that bodies are "temples of the Holy Spirit within us" (1 Cor 6:19). Biblical precedent for a health-based case for vegetarianism also appears in the Book of Daniel. Daniel and three others refuse King Nebuchadnezzar's rations of food and wine – consuming only "vegetables to eat and water to drink" – and emerge appearing "better and fatter" than those who had been eating the royal fare (Dan 1:8–16). Daniel's intent, however, was to avoid ritual defilement, and so like health considerations in general, this story supports restricted meat consumption more than unconditional vegetarianism.

Historically, a more common point is the conviction that meat eating leads to vice. Gluttony is of course one of Christianity's so-called seven deadly sins, and gluttony and meat eating have often been linked. Ironically, the association between the two may lie behind the Gospels' description of Jesus as a "glutton and a drunkard" (Mt 11:19; Lk 7:34). The comment may be intended to draw a polemical contrast between Jesus and John the Baptist, who practiced a more ascetic lifestyle, or it might merely reflect Jesus' willingness to share meals with the righteous and sinners alike. In any event, Christians have often thought that consuming flesh would fuel various sinful habits and desires, including alcoholism, sexual urges, anger, aggression, and other base instincts. This is partly why Rev. William Cowherd, who in 1809 founded the English Bible

Christian church, required church members to sign a pledge forswearing both meat and alcohol.

The earliest Christian vegetarians, however, practiced vegetarianism for reasons that were more directly spiritual. Their asceticism resulted from the belief that meat eating is a luxurious indulgence that interferes with spiritual communion with God. The self-denial involved in eating only simple plant foods helps orient one's thoughts away from materialistic, earthly concerns and helps focus attention on the divine. Such was the main rationale of the early Desert Fathers and the monastic vegetarians commonly found in eastern Christianity (Grumett and Muers 2010).

Vegetarianism as a spiritual discipline is quite different than the religious interests that motivate Paul's discussions of meat eating in the New Testament. Paul's overriding interest is to preserve harmony in early church communities and to win new converts; there is no indication that he thought meat eating in and of itself is spiritually significant. What matters for Paul are the social circumstances and spiritual attitudes surrounding flesh consumption. He cautions against eating meat offered to idols that could become a "stumbling block" to those who are "weak" (1 Cor 8:9; Rom 14:21). The point is not to denigrate vegetarians but to protect those who are weak in their faith from sliding back into paganism. "If food is a cause of their falling, I will never eat meat, so that I may not cause one of them to fall" (1 Cor 8:13). He directs both those who eat meat and those who abstain from it from passing judgment on each other (Rom 14:2; Col 2:6). But absent its effects on others, "If I partake with thankfulness, why should I be denounced because of that for which I give thanks?" (1 Cor 10:30–31) Paul also characterizes abstinence from food as the "teachings of demons," since everything created by God is good and as long as it is received with thanksgiving, "nothing is to be rejected" (1 Tim 4:1–4).

Jesus and Vegetarianism

Naturally, Christian ethicists also invoke Jesus to make the case for vegetarianism. One tactic is to

cite frequent references to animals in Jesus' teaching, such as the common characterization of his followers as sheep, or the analogy between fish and converts to his mission. A more ambitious approach is to argue that Jesus himself was a vegetarian (Akers 2000; Vaclavik 1989). The non-canonical Gospel of the Ebionites made this claim, according to Epiphanius, and Eusebius recorded that James, the brother of Jesus, was a vegetarian.

Contemporary scholars generally reject the suggestion that Jesus was a vegetarian, however. The bulk of the historical evidence points in the opposite direction, although the point is clouded by the fact that Jews of Jesus' time tended to draw a stark moral distinction between fish and land mammals. Jesus is depicted as consuming fish after his resurrection (Lk 24:42) and as giving fish to others (Mt 14:19–21). As a peasant Jew, it is doubtful that he ate meat other than fish regularly, but nothing in the Gospels suggests that he avoided eating animal flesh as a matter of principle. Had he done so, it seems likely that the Gospel writers would have found it worth noting. The Gospels disagree as to whether the last supper occurred as the Passover meal; if so, lamb was presumably served. Mark quotes Jesus as declaring all foods clean (Mk 7:19), a point affirmed by Paul (Rom 14:14).

A more promising strategy is to maintain that although he may not have advocated or practiced it himself, vegetarianism is a cogent extension of Jesus' emphasis on compassion and love. The Beatitudes, often taken to reflect the heart of Jesus' moral message, emphasize generosity towards the poor and meek (Mt 5:3–12; Lk 6:20–22). Since animals too are weak and vulnerable in relation to humans, true Christian ethics requires regarding animals as appropriate recipients of mercy and care, or so many have argued. Granted, in several places Jesus sharply contrasts the value of human life with that of animals (Mt 6:26, 12:12; Lk 12:7, 24). But he also was a consistent servant to those most in need. He healed the sick, kept company with lepers and prostitutes, and washed the feet of his own disciples. Also, loving your neighbor as yourself is one of two great commandments Jesus uses to sum the

content of the moral law (Mt 22:39). Arguably, this reference to "neighbors" should be understood inclusively, as properly encompassing both humans and nonhumans alike, even if Jesus himself would not have understood it this way (Miller 2011).

Along these lines, numerous Christian thinkers have defended vegetarianism out of respect for animals. Prohibitions on cruelty to animals have always been part of the Christian tradition. Various biblical passages indicate a human duty to relieve animal suffering (Prov 10:12; Exodus 23:5, Deut 22:4), and others command not subjecting animals to harsh treatment (Exodus 20:10, Deut 22:10; 25:4). Albert Schweitzer generalizes the point, describing "the ethic of reverence for life" as the "ethic of Jesus brought to philosophical expression" (Schweitzer 1999, p. 149). However, since Schweitzer's argument relies on an assumption from Schopenhauer's metaphysics – namely, the idea that all living creatures have a deep-seated "will-to-live" – its impact on other Christians has been limited. Karl Barth is another prominent example. He characterizes killing animals as a deeply reverential act of repentance. Given its destructiveness and capacity for inhumanity, it is permissible only as an expression of praise. Barth's case also has an eschatological thrust. He writes that vegetarianism is "a wanton anticipation of the new aeon for which we may hope" (Barth 1961, pp. 255–256).

The most prolific recent defender of Christian animal-based arguments for vegetarianism is Andrew Linzey. In early works, Linzey develops a case for animal rights on religious grounds – "theos-rights," as he called them – in a way intended to distance his position from secular animal rights arguments made by Peter Singer, Tom Regan, and other philosophers in the 1970s and 1980s. For Singer, what matters is that animals have sentience (Singer 1983); for Regan, it is the fact that animals are "subjects of a life" (Regan 1985). Linzey's view, by contrast, is that animals have rights only indirectly, as a result of "God's rights in his creation." God's creatures have value not from "any faculty or capacity, but in the will of God, which may be deduced from the givenness of spirit-filled individuals" (Linzey 1987, p. 76).

Later works feature a different strategy. Seeking to turn traditional theological defenses of meat eating on their heads, Linzey argues that the fact that animals lack souls hardly sanctions eating them. Since they have no chance at an afterlife, their time on earth is especially precious, which means that man is responsible for protecting them (Linzey 2009). Linzey grants that humans and animals differ in moral status but denies that this justifies meat-intensive eating habits. Throughout his career, Linzey has been a gradualist, calling not for an end to meat consumption altogether, but for drastically curtailing the use of animals for food and experimental purposes.

Environmental Concerns

Christian principles also support a different case for vegetarianism. In ways that were not true a hundred years ago, meat production in much of the world today has very harmful environmental and human costs. A large share of the world's grain harvest goes to feeding livestock, grain that could be used much more efficiently to alleviate hunger in many parts of the world. Animal farming also contributes more to global greenhouse gas production than transportation and produces vast amounts of animal waste and pollutants. Raising billions and billions of animals for food places a tremendous burden on the world's water and land resources; millions of acres of tropical forest have been cleared over the past couple of decades to make room for cattle grazing. Given that populations in emerging countries like China and India increasingly emulate Western dietary preferences, adverse environmental effects of meat eating will continue to escalate (Wirzba 2011). Since these effects will fall disproportionately on the world's poorest and most vulnerable, many recent authors stress that meat consumption is incompatible with the Gospel message of compassion, stewardship, and love for neighbor. For example, John Barclay contends that Paul's pragmatic contextualism implies vegetarianism as a new Christian imperative. "Our consumption of meat could literally cause the death of others, and it is impossible to square this with the Christian duty of

love towards all those for whom Christ died" (Barclay 2010, p. 593).

A similar but more politically tinged version of this argument also has been made. Scholars often note that Jesus' meal-time inclusiveness – his practice of "open commensality" – was not merely a display of good hospitality. In its social and historical context, it also served a radical and subversive function. Jesus' outreach to clean and unclean alike, to both social outcasts and power brokers, was a strike against prevailing social boundaries and divisions. The Roman imperial economy had disastrous effects on peasant farmers and laborers, and the Romans were assisted by elite Jews who collaborated with them. Jesus' outburst in the Temple was not merely a reaction to perceived religious desecration, but a symbolic demonstration against Roman and Jewish power structures. It was a decidedly political act. Early Christians commemorated Jesus and his message not by eating meat, but by the communal breaking and sharing of bread, one of the humblest of all foods (Northcutt 2008). Just as Jesus used meals to protest oppressive powers of his age, by boycotting meat, contemporary Christians can likewise use their eating practices to resist some of the most destructive and degrading manifestations of present-day economic industrialization.

Summary

Despite being a minority view within the tradition, growing numbers of Christians see vegetarianism as an important, faith-based response to the contemporary world. While the Biblical evidence in favor of vegetarianism is mixed, most recent authors point out that the contemporary context is importantly different from that when the Bible was written. People today, especially in the affluent West, have many healthy nonmeat choices available to them, and the industrialization of modern farming has made the production of meat more objectionable than it was 2000 years ago. One sign of a change in perspective can be seen in a recent statement by Pope Benedict. He writes, "the natural environment is more than raw

material to be manipulated at our pleasure; it is a wondrous work of the Creator containing a ‘grammar’ which sets forth ends and criteria for its wise use, not its reckless exploitation” (Benedict XVI 2009). Increased environmental pressures brought about by overuse of the earth’s natural resources, chronic food shortages in many parts of the world, and the massive animal suffering involved in industrialized meat production are likely to keep the topic of vegetarianism on the agenda of Christian ethics for a long time.

Introduction

Food in the form of items with nutrients essential for survival (whether cooked or uncooked) is of key importance for the distinct Christian theological and philosophical perspective called “Christian Mysticism”: it acquires a new spiritual and transcendent dimension. After an attempt to define and chart the rather loosely connected threads in philosophical and theological thought that can be grouped within this distinct form of mysticism, attention will be directed to the significance of food and drink for the achievement of the goals of Christian Mysticism and thus, the *soteriological*

transformation of human beings. The discussion will close with an evaluation of the contribution of Christian Mysticism in the context of contemporary debates in the Philosophy of Food.

The Key Characteristics of the Christian Mystical Approach

The mystical direction or school of thought starts from the very early stages in the development of Christian Philosophy and Theology. It is widely accepted that the Christian Church was founded in a mystical filling with the Holy Spirit, with the Apostles forming the first community of Christian mystics (Fanning 2001; McGinn 1991). Christian Mysticism, in the form of both *mystike theologia* (mystical theology) and *praktike filosofia* (practical philosophy) is not (only) a way of seeing reality but also a way of life. According to Underhill: “The essence of mysticism being not a doctrine but a way of life, its interests require groups of persons who put its principles into effect” (Underhill 1932). As such, one can see this way of life in the very early Christian communities, who saw in the New Testament and in particular the Gospel according to St John the Evangelist and the Epistles of St Paul the kernel of their esoteric canon of spiritual and intellectual development. Early Patristic texts from key mystics (St Gregory of Nyssa, St Augustine, the Areopagetic texts, St Maximus the Confessor, and others) soon became (in both the Medieval West and the Byzantine East) the set canon textbooks for initiation in the mystical Christian philosophical and theological tradition. The first five centuries provided the basic formative context for the later development of Christian mysticism and formed the basic context of the Christian mystical tradition (King 2003). This tradition became continuously enriched with new Mystical approaches, core texts, and methodologies in the first millennium, culminating in the famous proliferation of Mysticism in middle and late Medieval and Byzantine Philosophy and Theology (ca. 1000–1500) and early Renaissance. Putting aside the significant differences between the Western Medieval and the Eastern Byzantine mystical approaches,

attention now will be directed to the depiction of some common themes and trends for the period till the sixteenth century in the form of the following key characteristics:

1. It cannot be described in terms of subjectivism versus objectivism (both in terms of epistemology and ethics).
2. The mystical experience is veridical (i.e., one can say when one has it), but, for its most important and key forms, it does not obey the laws of traditional logic and reasoning (there is, presumably, a new epistemology involved).
3. Body and soul are not divided, but they are unified in the attempt to achieve the mystical union of God and creation through illumination and deification.
4. According to many of its most profound and dogmatically conscious forms, Christian Mysticism cannot accommodate intellectualism nor a conceptualism (traditionally conceived) because all reasoning, imagination, and memory of sensory images are to be avoided; the organ of chief importance for the mystic is the heart and not the mind. It is important to note in relation to this feature that true Christian mysticism should not be transformed into some kind of sensualism or emotionalism, since emotions and senses of the body are also to be avoided in the attempt to unite with the triune God. Christian mysticism also should be distinguished from philosophical esotericism, since the early mystical Fathers tried to distance themselves from the Neoplatonist and Gnostic forms of philosophical esotericism of their time.
5. In some of the most important forms of Christian mysticism, the mystical union can be achieved while alive and with the body; further to this, later Byzantine and hesychastic mystics, such as St. Gregory Palamas (1296–1359) and St. Nicholas Cabasilas (1319/23–ca. 1391), emphasize that this union is achieved via the divine energies and acts and not the divine essence (the triune God is infinitely more than the sum of His acts and energies).

While acknowledging that Christian mystical ideas were further developed and advanced in the

subsequent five centuries, most of the important key characteristics were developed already by the late fifteenth century. So, it will be sufficient to take the above key characteristics as forming an acceptable set of what can be termed as “the Christian Mystical Tradition.”

Food in the Christian Mystical Perspective

Food is treated as of key importance in the New Testament: Jesus abstained from food for 40 days, before He starts His role as a teacher (*Matthew* 4:2). He also responded to His disciples that “My food is to do the will of Him who sent me and to accomplish His work” when asked if he was hungry and wanted to eat (*John* 4:34). The early Christian mystics took it for granted that when one considers food, one has to have in mind that it was because of the wrong food consumption that Eve and Adam were expelled from Paradise (*Genesis*, Chap. 3). This theme was repeated in the mystical writings of many early Fathers and became a standard reference in Medieval and Byzantine mystical literature. Food in this way acquired a mystical significance and meaning that was ontologically related not only to the Old Adam (Adam after expulsion from Paradise) but also to the New Adam (i.e., the ontologically transformed human after deification or illumination) that the mystics tried to exemplify with their illumined life. But how is this conceptualization of food related to the Christian mystical theology and philosophy and the role of the New Adam in creation?

From the above discussion of the main characteristics of Christian Mysticism, one can see how impossible for a mystic is to be *anthropocentric* (i.e., to regard *anthropos* or human as the focal point of all meaning and value) when creation becomes the focal point of any investigation. Also, one can see how alien should the mystical way of life be to established rules of human reasoning, if it is to achieve the desired goal of union with the triune God. It is also evident that humans can (and should) achieve a new awareness of their role in creation and of how they should behave towards other creatures, during the *ecstatic*

rapture that the mystical way of life entails. This issue can become clearer if we look at characteristic examples of Christian Mysticism: the areopagetic texts (which were texts attributed to St Dionysius the Areopagite, the pupil of St Paul, probably written around the sixteenth century), St. Symeon the New Theologian (949–1022), and St Nicholaos Cabasilas (ca. 1319–1392).

The areopagetic text *Epistle to Titus* makes some rather common place by its time of creation remarks about the mystical significance of food, in solid and liquid form. Food in solid form is the mystical knowledge achieved with the help of Divine Wisdom through the senses (in the form of a stable, unifying, and indivisible knowledge that provides solid nourishment for the spirit), and food in liquid form (cited forms: dew, milk, water, wine and honey) is the actual divinations or illuminations that make deification possible and effected: water gains the mystical power of eternal life, wine a mystical revival and strength, and honey provides purification and preservation. And through them Divine Wisdom produces a veritable good cheer that both nourishes and perfects (*Epistle to Titus*, *Hierarch*, Sect. IV; Dionysius the Areopagite 1897). Creation and food produced and acquired through it thus gains a mystical role in salvation. This theme is further elucidated and enhanced in the works of the later Byzantine Saints: St Symeon the New Theologian and St Nicholaos Cabasilas.

Actually, St. Symeon the New Theologian emphasizes that any kind of animosity or improper attitude towards creation is the result of Adam’s fall from heaven and comes as a result from it. Mystical union with the triune God will not only return man to the mode of existence he had before the Fall, but it will return in him the wonder and full respect with which he needs to regard God’s Creation (*Hymn* 32). He further on claims that the use of material goods and creation for man’s survival is not evil but it should be carried out with no “desire of the flesh,” no “desire of the eyes,” and no “vain thoughts” (*Catechetical Orations*, 5). This further supports St. Symeon’s conviction that if a man is to be united with God mystically, he must do so with a complete transformation of his desires, arrived at through the

ecstatic love towards the Creator and the consequent abstention of any thought and behavior that is not directed by this ecstatic love towards the Creator. Man thus becomes not only a guardian of Creation through asceticism but considers it as an invaluable means for his salvation; this forces upon him a transformation of his desires and the way he looks at Creation (Krivocheine 1986; Kesselopoulos 2001).

This mystical perspective has many advantages over the traditional philosophical and theological contemporary approaches to the problem of feasting in a world that requires fasting:

First, it is not dividing the world into the realm of the subjective and the realm of the objective, or (put in other terms) between the body and the mind, the material and the immaterial. As indicated above, both matter (body) and spirit are united in the mystical union in a new form of hypostatic existence.

Second, it allows for a new non-anthropocentric epistemology and ethics: man does not exist for himself, but *for God*, and Creation is the place which God created for man's salvation. In his ecstatic love towards God, man cannot regard the world for his own means and interests but through his ecstatic love towards God (Athanasopoulos 1999).

Even though these advantages are a real improvement on the philosophical and theological impasse in contemporary debates, how is the demand for sanctification of nature to be met with this perspective in mind?

Vegetarians and vegans here may come back to indicate that this mystical standpoint may be interpreted as indicating that man has the role of a simple attendant or housekeeper and thus Nature may be regarded as part of the household items such a housekeeper attends to, with no further responsibility or value to him. But St. Nicholas Cabasilas claims that it is here that man's role in the Divine Eucharist as returning Creation to its rightful place can be most clearly envisaged.

Man, in the process of the Divine Liturgy, and while performing the sacrament of Eucharist, offers to God what is made by God (the priest announces

in the Eucharist while offering the Holy Gifts that he offers them as of God's to God: *ta sa ek ton son soi prosferomen*). Cabasilas stresses that the part of Creation that is offered in the altar is not man's but God's. By offering to God what is God's, man enters into a mystical union with the triune God and becomes united with Him through grace, placing Creation in the proper *soteriological* perspective. By re-consecrating nature and creation within the process of the Divine Eucharist, man finds his true role in Creation, becomes light himself, and mystically unites with God, radiating light back into Creation. Man does not exist to use nature and creatures but to consecrate them and refer them back to their rightful Owner and Creator. And man, according to Cabasilas, can only do this once he lives through the mystic life of the consecrating Church and its mysteries. It is only through the mystical realization of man's failure to be a true son and making of God that man can realize and achieve the mystical union with God (Cabasilas 1960).

Through the mysteries of the Church and most importantly the Divine Eucharist, where bread and wine are offered and become the Blood and Body of Christ, man becomes holy again, and with the return to his holiness, he can further sanctify nature and offer it to God. Cabasilas here is in full agreement of the Orthodox Mystics before him, in claiming that the "naming" of Creation by man during Creation (*Genesis*) is part of this re-sanctification of Nature. Man was created to sanctify Nature and not destroy it according to the Orthodox Mystics.

It is important to emphasize that what is offered in the Eucharist is not owned by man. Man is utterly naked, defenseless, with no justification, and without pretense, when facing his Creator. The mystery of the all powerful grace and mercy, thus, becomes the true *soteriological* and *sanctifying* force.

Man performs a *reasonable* sacrifice of his will over things and himself to gain the object of his ecstatic love, without losing his personal and hypostatic characteristics, so that he can find what he ecstatically loves and desires. Trying to explain the words "reasonable sacrifice" in the Divine Liturgy, Cabasilas claims that the

sacrifice is *reasonable* because it is *mystical*: the priest, by pronouncing the appropriate words, does all that is necessary to make the offered part of Creation holy again and suitable for sacrifice to God, bringing man back into his true role in Creation, in accordance with the *Genesis* book in the Old Testament (Cabasilas 1960).

According to Cabasilas, “the *sacrifice* is truly *an act and a reality*,” and even though the priest only says specific names and words, these become significant and mean far more than perceived by human ears, through the mystery of divine grace, in the same way that in the *Genesis*, man by naming nature he is not just saying names and words empty of mystical and theological significance. It is important to emphasize that this *use of names and words* lies within the mystical tradition of the Areopagetic texts. It is through the names of God that we can gain a mystical awareness of His *apophatic* and *cataphatic* realization and, thus, be led into a mystical union with Him. In the same way, it is through the *naming* process and, via this process, the re-sanctification of Nature, that we can achieve the mystical union of God with creation. Man thus, becomes *synergos* (i.e., collaborator) in salvation with God, gaining himself a new *soteriological* perspective.

Cabasilas in a text, where he explains the difference between the new and the old Adam (man after and before the Fall), put forward the following ideas: the true bread (*o alethes artos*) is Jesus Christ, who, in the same way that the usual bread strengthens man’s heart and gives him physical strength, came down and brought a new form of life and strength. It is Him (Jesus) that one should strive to incorporate within constantly, to be preserved in the constant and continuous time of hunger (*limon*) that one lives in while on this earth (*Patrologia Graeca*, vol. 150).

The above remarks are relevant not only for the development of Christian Mysticism in Byzantine Civilization but are equally valid for Medieval Europe. Examples are abundant in the writings of Johannes Scotus Erigena (810–877), Bernard of Clairvaux (1090–1153), Richard of St Victor (ca. 1120–1173), works related to Francis of Assisi (1182–1226), Bonaventura (1221–1274), the Cistercians and the Beguines, Meister Eckhart

(ca. 1260–1327/8), and others (Fanning 2001; King 2003;? Walker Bynum 1985).

How the Christian Mystical Approach Relates to the Contemporary Philosophy of Food

In current ethical discussions about the consumption of food, there is a growing tendency to provide arguments in terms of the rights and duties of the people and beings involved, either recognizing in them intrinsic qualities, which can justify the existence of human duties towards them and their rights for respect by humans, or by linking them to the rights and duties of others, who have some interest in the consumed animals’ fate or well-being. So, for example, in the case of some philosophical arguments put forward by vegetarians and/or vegans, animals should not be consumed and in general all suffering to them should be restricted, if not avoided at all costs, on the basis of their inherent moral qualities and their well-being. This places ethical restrictions on what one can eat and drink and, in some way, forces a fast upon humans on moral considerations. Thus, in general, the argument for an abstention from all meat and dairy products is that one should not eat meat nor drink milk, because either this action makes animals feel pain/discomfort or because such an action reduces the well-being of other people in the developing world (since the resources used to feed animals can be used to feed starving people). In both cases there is some sort of a contract involved (between humans and the animals or between humans in more and humans in less-developed countries) and through the consumption of specific foods and drinks one breaks the moral rules of this contract.

Some philosophers (e.g., Peter Singer and Tom Regan) actually go to the point of making parallelisms between the “speciesism” that existed between people of different colors and races in the recent past and the *biological* now *speciesism* that exists between humans and the rest of the animal kingdom (cf. Singer 1975; Regan and Singer 1976). They make the claim that the same moral rules that bind the different human races and form a contract that is

sanctioned by international legal documents and agreements (such as the United Nations Declaration of Human Rights) bind humans as well to the rest of the animal kingdom.

This approach has influenced a large part of the relevant current bibliography on the ethics of food and the 1970s texts discussing the “speciesism” approach are now standard textbooks in Environmental Ethics and any set bibliographies on the Philosophy of Food and Drink.

It has been pointed out however, from the early 1980s, that the Singer-Regan approach cannot offer convincing arguments in its support. It is not only that the contract theory that it alludes to is fallaciously entertained (since there is a need for a further proof that animals – or other, even future, people concerned – can take part in such a contract and that they can both represent and promote their interests through this contract), it is also that for many adherents of vegetarianism or veganism, the contract theory (or any theory based on duties and rights) is not a good way to put forward their viewpoint and arguments for the intrinsic value and sacredness of animals, plants, and the other beings that exist in the world but are not created nor produced by humans. They make the point that even if a human being was the last person on this earth with the possibility of destroying earth and all the beings on it after his/her death, it would be morally wrong to do so, not on any contracts (which would not hold after death in any case), but on the grounds that nature and everything non-human made is intrinsically valuable with a value that is independent of any human consideration, making them *sacred*. They also point out that resorting to anthropocentric values and moral qualities (e.g., moral virtues or elaborate rule and/or contract theories) would not satisfy their requirements, since they claim that nonhuman made beings cannot be examined in human terms and human categories of thought.

Philosophical discussions about the consumption and production of food thus need a fresh air that will provide new sets of arguments, quite distinct from traditional conceptions about human rationality and its modes of operation. As indicated above, Christian mysticism can provide an alternative which will allow for the *re-sanctification* of nature that is necessary to

get contemporary philosophers and theologians out of their philosophical and theological impasse.

Summary

Feasting and fasting, as primarily concerned with the way humans grow and sustain themselves, should not be treated as unimportant nor as not directly concerned with the way one can gain self-knowledge and self-understanding and knowledge and understanding about the external world and Man’s relation with God. Mystical metaphysics and ontology here are interconnected with Mystical anthropology and ethics. Within Christian Mysticism, asceticism exists not for the mortification of flesh but for the reorientation of our intellectual and volitional powers. Food and drink thus become means of spiritual nourishment: the priest in the mystery of the Divine Eucharist offers parts of creation to God in the form of a “reasonable” sacrifice, but neither the gifts offered nor the words used belong to the priest, who is with no pretense and no justification. Creation becomes thus autonomous and can only have a separate existence from God, when it *lacks ecstatic love*, the true criterion of the mystical way. Creation and man, in a world void of ecstatic love, thus, become both alienated and alienating. Both feasting and fasting should become one and have as their goal the mystical transformation of the human will, so that it can unite and reside in God’s Will.

Introduction

There is no normative Christian view on any subject, let alone one as comprehensive as perspectives on food and agricultural ethics. The subject is further complicated because there are over two billion global Christians. Rather, it is more accurate to speak of “Christianities,” given the diverse cultural, historical, geographic, and institutional histories of Christianity. As a result of this diversity, this entry can but make reference to key guiding ideas, debates, theologians, food activists, farmers, and lived practices in regard to various food and agricultural ethics that have manifested throughout Christianity’s diverse history, up to its even more diverse present, with a special focus given to Western Christianity.

Christianity arose within a cultural and geographical context that was shaped by Hellenism, the Roman Empire, various mystery cults, and diverse Israelite cultural and political identities. To understand the development of Christian views of agriculture and food, it is important to have a cursory understanding of dominant themes about nature, food, and agriculture that were present in these other groups, as their politics, cultural views, and engaged practices influence early, and even some contemporary, Christian perspectives on food and agriculture (Glacken 1967; Feeley-Harnik 1994).

Cultural Milieu of Early Christianity

Greek Hellenism

The ancient Greeks had a plethora of philosophies and deities and were a mixture of early cities surrounded by agricultural fields. A famous Socratic dialogue from Plato suggests that an antipathy toward the countryside, and nature broadly, existed in ancient Greece. In his exchange with Phaedrus, Socrates mentions that knowledge is to be found in the city, and not in the bucolic country. This Socratic chain of thought mixed with Plato’s realm of pure ideal forms, leading some scholars to postulate that in Greek society there appeared certain dualisms, or what ecofeminists call a logic of domination, where one half of the dualism was privileged over the other:

city over country and ideal forms/ideas over the world of flesh/nature. These ideas were married with an Aristotelian view of the cosmos that assumed a great-chain-of-being, with the observable universe based on the four elements: earth, air, fire, and water. Taken together, it is postulated that this view of humanity and nature generated an incipient anthropocentrism that influences Paul's letters (Romans 1:24–25 and Philippians 3:21, but see also Psalm 8 and Psalm 115 for evidence that such cultural views predate Paul) and thus early Christian understandings of nature, especially in the divide between a fallen, corporeal body and earth and a transcendent soul that is bound for heaven or hell for eternity. It should be noted, however, that Hellenistic Greeks also actively attempted to cultivate a working knowledge of their landscapes, seen in the plant geography of Theophrastus' *Enquiry into Plants* and in advancements they made in plant and animal breeding. Altogether, though, "there are substantial reasons for believing the roots of modern attitudes toward nature are to be found in the Hellenistic age" (Glacken 1967), and these roots are based upon city/country and human-nature distinctions, distinctions that largely carry over to Christianity and Christian agricultural ethics, past and present.

Rome

Rome was built upon Greek Hellenism, and as Rome grew in size, so did its ecofootprint, as the Empire was built upon grids of roads and irrigated canals. Some posit that the Empire overexploited its soils, which is one of the main reasons it eventually collapsed. The Empire aggressively deforested the lands it conquered as it needed timber for building, and its population also cleared land to farm (Perlin 1989). Both Hesiod and Virgil, along with Seneca and Ovid, write longingly of a bucolic nature that brings humans closer to the gods through agricultural work. However, for the most part, these and other writings about agriculture in the Roman era recognize that the soils have been depleted and that the golden age of Rome was a more fecund, less toilsome time, when citizens were also physically and morally superior than those in the latter Empire. Besides

these views of a golden age, there also existed in Rome a cyclical calendar based upon various feasts and worship of various agricultural deities, some of which were related to mystery cults.

Israelites

Besides the dualisms found in Greek thought that manifest in Paul's letters and that shape centuries of Christian thought about human-nature-Divine relations, the other biggest contributor to historical as well as contemporary Christian views of agriculture and food comes from the Israelites. Jews at the time of the historical Jesus were diverse in political and cultural views, although they were still largely united under the Second Temple and its ritual practices based upon the agricultural calendar. Many scholars have written about Jewish agriculture and food, using archaeological and historical-critical methods to better understand the ritual and agricultural practices of this era of Israelite/Jewish history, and these writings expertly capture some of this diversity. Given space constraints, a cursory overview of proto-Jewish farming, food practices, and foodways is covered here.

The creation story found in the Hebrew Bible's Genesis 2:7 states that the first human, Adam, comes from the soil. This is the translation of the Hebrew term, *adama(h)*, out of which Yahweh/YHWH/God forms humans. This suggests the ancient Israelites had a nuanced understanding of their local environment and that as an agrarian and farming people, their conception of self was intimately tied up with their relationship with their farming lands and grazing herds (Davis 2009). This does not mean they practiced what today may be called sustainable agriculture, given their soil loss and exploitation of their ecosystems, but it does mean that food and agricultural practices and ethics figured prominently in their identity as a people (Hillel 2007).

Some of the agricultural practices mentioned in Torah include a sabbatical year for the soil so it may rest; companion planting; recognition of sacred grains and plants, including the Seven Species (Deuteronomy 8:8); the importance of fruit trees (Proverbs 27:18); and the covenantal gift of good land (Deuteronomy 8:7–10), to name a few. Yet there is also a tension, as seen in the story of

Cain and Abel, where Yahweh chooses Abel's offering of part of his flock, which some interpret at the benefits of pastoralism. However, out of jealousy, Cain kills Abel, and his punishment is to toil in the fields as an agriculturalist (Genesis 4:2–16), where the soil will not offer its strength or nourishment to Cain and his descendants. Some point to this passage as being an indictment against practicing agriculture, although as with any sacred text, and including especially the Hebrew Bible (Christian Old Testament) and the New Testament, there are multiple, and at times competing, interpretations of this and many other agriculture-related passages. For example, there is no one approach to interpreting, and thus basing contemporary farming practices on, the command to “till the garden and keep it” (Genesis 2:15).

Other agrarian and food-centered practices of the Israelites informed early Christianity. Mostly this was by shaping what Christianity was not, largely because the early Christian communities had to differentiate themselves to gain adherents and to open up the community to non-Jews (see especially Galatians 3:28). This is seen, for example, in what became known as the Final Supper, at which point Christian theologians argue/interpret that Jesus moved beyond the in-group Israelite-only Passover Seder and made the meal universal and inclusive for all via what becomes the practice of communion/Holy Eucharist. Nonetheless, these other Israelite food practices include a variety of blessings (*brachot*) over wine, water, meat, cheese, and other food items. Customary traditions also formed around saying blessings after food was consumed (*bensching*). The Israelites of Jesus's time also had a sophisticated ritualized calendar centered upon the power of the Aaronic priesthood in the Second Temple and that was based on an agricultural calendar. Some of the major Jewish holidays and Temple rituals centered upon food, most especially those of Passover (*Pesach*), the Feast of Weeks (*Shavuot*), and the Festival of Booths (*Sukkot*). Of final mention is the tripartite Torah law that required Jews to keep kosher (*kashrut*), with interpretation of these laws building over the centuries in the Talmud. Taken together, the agrarian cultural milieu of Judaism, coupled with the very clear Jewish

connection with food and agriculture in both dietary practices and ritual requirements and calendar, combined to make food a central element of Christianity.

Early Christianity and Food

Early forms of Christianity centered upon the life and teachings of Jesus and then especially the apostolic work of Jesus's original followers. After his death, the teachings and life of Jesus became codified after a few centuries in the New Testament. Because the early Christians were straddling the iterative worlds of Judaism and Roman paganism, they had to communicate Jesus's universal atonement through these mediums. One way of communicating this message was through food, food rituals, and diet (Jung 2006). Parables about wineskins (Luke 5:36–39), putting away anxious thoughts about food and drink (Matthew 6:25), and the metaphor of wine meaning being inspired by God (Jeremiah 23:9) all developed and were written down. There are also passages in the New Testament where Jesus and his disciples challenge Jewish food habits by interacting with and feeding non-Jews, including miracles of feeding the masses (Matthew 15:32–39 and Mark 8:1–9) and eating with Pharisees without washing hands (Luke 11:37–41).

As with the Hebrew Bible/Old Testament, the threat of a disciplinary famine and punishment of failed crops looms large for not following ritual and other religious protocol. This clearly suggests that some form of recognition existed about the fragility of agricultural production, although in an era without meteorology, the understanding for crop failures was related to concepts of sin and lack of fidelity to covenants.

Early Christian communities struggled with oppression under Roman rule until the Edict of Milan and conversion of Constantine. Once Christianity was made, the religion of empire, its power, and influence grew exponentially. One way it spread was through food and food customs, which coalesced around “four underlying themes: commensality, fasting, the sacrament, and bodily health” (Eden 2011).

While modern-day connections between soil health and bodily health motivate many who engage in sustainable agriculture and who discuss agricultural ethics, it would be a misrepresentation and faulty reinterpretation of the majority of Christian tradition(s) to see a clear concern for soil and livestock/animal health as being a focus of the myriad and various historical Christian foodways that developed over the centuries. The ongoing ecological Reformation of the world's religions, including Christianity, is a product of a post-Darwinian, post-ecological world of the last 150 years. It is also one which is slowly gaining in followers after the 1962 publication of *Silent Spring* and the 1967 publication of Lynn White, Jr.'s "The Historic Roots of our Ecologic Crisis," where Western Christianity was blamed as the culprit for ecological decline. The modern, industrialized world, including the industrialization of commodity agriculture, is very different than that in which major Christian theologians wrote, from Paul to Augustine to Aquinas, to the split between Western and Eastern churches, through the Reformation and era of European colonial expansion. None of the theologians and church leaders during these centuries had the benefit of microscopes and soil science, so knew nothing of soil formation and microbiology. Nor did they have the ability to use satellite imagery to understand how farming practices at various scales, using various chemical-based and irrigation-driven technologies, influence ecosystems, ecosystem processes and services, and the health of various life forms.

While there are examples that can be recovered and reinterpreted using modern-day ecological and sustainable agriculture lenses, such as Saint Francis and his views about nature, the historical reality is that most Christians, including lay, monastic, and elite leaders, operated within a cosmology of sin, fall, temptation, and redemption. Within this theological and cultural milieu, work in transforming the planet for human use (the "dominion over" of Genesis) was seen as the vocation of most Christians. God created *ex nihilo* and on this blank slate gave humans dominion and the power to name the animals and plants. As Christianity spread, pagans and their agricultural calendar and cycles were encountered, but these

were replaced by liturgical meals devoid of such traditional feasts. Furthermore, some saints, angels, and even the Virgin Mary became associated with aspects of food cultivation and celebration, but this occurred more at the level of lived religion and was not generally seen as orthodox teaching. Many scholars claim that the anthropocentrism of Christian Europe, coupled with the inherent brittleness of domesticated agriculture, led to the demise of the Middle East's and Europe's flora and fauna. They claim that this process was repeated on *terra nullius* in the "New World," where European seeds, farming practices, domesticated species, and religious views rapidly changed the cultural and biological landscapes of the Americas (Sale 2006). It is to this legacy of farming practices and teachings about creation that contemporary Christians are responding, with a major avenue being through revisiting, reinterpreting, renewing, and creating afresh new perspectives on food and agricultural ethics.

Contemporary Christian Views on Food and Agriculture

Growing numbers of Christians the world over, from laity to positions of leadership, are revisiting Christian views of agriculture. These views include reevaluating Christian duties and ideals as consumers of food products and also as producers and growers of food products. Agricultural ethics broadly are "concerned with the values and moral issues involved in food production and farming practices" (Haynes 2009). The larger category of ethics, or questions of good/bad, good/evil, and morally obligatory/avoidable actions, as well as issues about duty, virtues, and justice, is also central to religion, while specific ethical issues have been central to Christianity since the time of Jesus. It should come as no surprise then that ethical deliberations about religion and agriculture are emerging in response to the industrialization and globalization of the world's food supply; such concerns are also being influenced by increasing knowledge about climate change, the relationship between food and physical health,

and the increased popularity of alternative food movements. The remainder of this entry investigates some of the varieties of contemporary Christian perspectives on food and agricultural ethics, where these perspectives focus on issues of food and agricultural justice, and sustainable food praxis. This investigation includes highlighting key thinkers, farmers, and emerging theological perspectives about food and agriculture.

Two of the most well-known Christian advocates for sustainable agriculture are the North Americans Wendell Berry and Wes Jackson. Berry is famous for bridging the gap between the Western, and later, North American, agrarian lineage and the ecological sciences. He uses sustainable farming practices on his farm in Kentucky and his experience as a farmer influences his poetry, essays, and novels. His 1977 classic, *The Unsettling of America: Culture and Agriculture*, is one of the first sustained critiques about the corporate takeover of industrial agriculture and the impact this has had on America's rural farming communities. While his personal faith is not central to his nonfiction work, it repeatedly enters into his poetry, essays, and fiction work, so that his Baptist views readily inform his perspective on agriculture, the American extractive economy, and Christianity at large. Berry is therefore probably the most well-known and most quoted advocate of a modern-day Christian sustainable food and sustainable agricultural ethic, one grounded in agrarianism and thrift, where humans are seen as utterly dependent upon the miracles of seed and soil.

For Berry's theocentric, Biblical view of agricultural ethics, our duties are to generate cultures of place that are embedded within bioregions. These cultures of place should actively work to cultivate the soil through sustainable animal husbandry and sustainable agricultural farming practices. As Berry writes, good farmers "take seriously their duties as stewards of Creation and of their land's inheritors, [and] contribute to the welfare of society in more ways than society usually acknowledges, or even knows. These farmers produce valuable goods, of course; but they also conserve soil, they conserve water, they conserve wildlife, they conserve open space, they conserve

scenery" (2009). For Berry these valuable goods are produced within a context of being stewards of Creation, such that Berry's ecological agrarian ideals are thoroughly influenced by his own reading of the Bible and his own life long involvement in Christianity.

Berry has cultivated and produced this Christian view of food and agricultural ethics in dialogue with his contemporary, the plant geneticist Wes Jackson. Jackson and Berry began a mail-based correspondence in the late 1970s, and this correspondence developed into a lifelong friendship, where the two have explored cultural narratives and views of farming and how these influence farming practices. Jackson is best known for the work he is undertaking at the Land Institute, a research station he began with his wife in Salinas, Kansas, where the Institute is attempting to develop perennial polycultures that mimic the original ecosystem of the Great Plains (Jackson 1985). Like Berry, Jackson is an advocate of sustainable agriculture and is critical of reductive, mechanistic science and its impact upon the Green Revolution. He is also a vocal critic of the industrialization and perceived corporate takeover of modern agriculture. Like Berry, Jackson is also a Protestant, so that his views of agriculture are influenced by his reading of the Bible.

Taken together, Berry's and Jackson's respective work as writers, farmers, and lay theologians/interpreters of scripture, coupled with their popularity in scientific, academic, farming, and Christian communities, has helped create the foundation of contemporary Christian sustainable agricultural ethics. Their influence is seen in other leading Christian farmers and sustainable food advocates, ranging from Joel Salatin of Polyface Farm; to Sister Miriam MacGillis of Genesis Farm (equally influenced by Father Thomas Berry); to the agronomist Gary Fick and his treatise *Food, Farming, and Faith* (2008); to the Christian organic farmer and distinguished fellow at the Leopold Center for Sustainable Agriculture, Fred Kirschenmann (2010). Salatin has become a well-known "crusader," whose articulate criticisms of post-Green Revolution agribusiness and corporate farming have earned him a following. He presents

himself as a humble libertarian farmer who lives in rural Virginia and who sees his farming as being inspired by Christian views of stewardship of the environment. His farming practices include free range pasturing of cows, chickens, pigs, and other animals; on-site humane slaughter; rotational grazing; and growing of polycultures, and he is active in training the next generation of farmers by offering on-farm internship positions. MacGillis is inspired by the agricultural insights of Wendell Berry, but more so the Universe Story and the teachings of Thomas Berry. These sources influenced MacGillis, under sponsorship of her Dominican congregation, to turn their farm into a biodynamic Community Supported Agriculture campus and teaching center where organic farming methods have been practiced since 1980. This pioneering work has resulted in MacGillis becoming recognized as a leading voice in Catholicism and especially among Catholic women religious, advocating for Christian agricultural ethics that support sustainable practices. Gary Fick is an agronomist at Cornell University, whose 2008 book marries his Protestant reading of the Bible with years of researching sustainable agriculture issues, leading him to write about 15 essentials of agriculture based on Biblical insights. This list ranges from respecting and protecting soil to being concerned for farm animal welfare, to maintaining soil fertility, to providing a living wage for farmers, to recognizing that agriculture has profound religious and ethical components, including the assurance that each person is fed so they can celebrate life and fulfill God's plan for them. Lastly, Fred Kirschenmann uses organic farming methods to farm his family's North Dakota farm and is a leading activist-scholar researching and writing about sustainable farming within a North American University context. Kirschenmann has developed an incarnational understanding of God/Christ, where he believes that God/Christ is present in all beings, and in all on-farm relationships, that are found on farms: from animals eating, mating, procreating, and dying to plants seeding and growing, to the harvesting and eating of farm products. For Kirschenmann, this incarnational relationship recognizes the divinity in all relationships on a farm

and in farm soils, so that sustainable farming becomes a vocational act that allows a farmer to help tend to the Garden of Eden while serving the tree of life contained therein.

The above Christian sustainable food advocates have been instrumental in developing a modern-day Christian-based agricultural ethic that takes sustainable farming as its central point of view. This ethics contains concern for farm workers, farm land, and natural resources; advocates for living wages; is concerned with food justice and food access issues; and takes seriously the biblical task of being stewards of God's creation. Many Christians who advocate for sustainable agricultural ethics can be labeled as theocentric, while some might be considered pantheistic, while still others are evangelical and more conservative with their understanding of the Christian God. The stewardship ethic is also spreading into Global Christianity, with African churches becoming involved in permaculture; Latin American churches becoming involved with land issues and peasant agriculture issues; to food activists reinterpreting biblical teachings such as gleaning from the fields, where they are bringing excess crops to food banks and homeless shelters; to Catholic Worker Houses using sustainable farming methods to grow food that is then served to homeless people. In terms of institutional teachings, the United States Conference of Catholic Bishops has made a clear call for the practice of sustainable agriculture, and the Conference links such practice with issues of environmental justice (2003).

Despite this fecund growth in contemporary Christian sustainable agricultural ethics, the above leaders, farms, and movements should not be interpreted to represent the majority of Christian views about contemporary food and agricultural ethics more broadly. Rather, concern about food and agricultural ethics are still relatively low for most global citizens, at least in industrial and post-industrial nations, although the contemporary movements outlined in this entry are gaining in adherents and popularity, and this extends into a variety of Christian demographics. The recent trends suggest that more institutional bodies are beginning to speak about food issues from the

contexts of physical health, community health, and/or planetary health and are connecting such concerns to Christian and biblical teachings. Trends suggest that concern about contemporary food issues will continue to grow in Christianity, with a slow but vibrant growth in concern about sustainable agricultural ethics (Wirzba 2011).

Two areas of many where there is still contention about Christian perspectives on food include contemporary Christian views about population growth and about genetically modified organisms being used in food and agricultural production (Bruce 2009). Where Christians might align on these issues in part depends upon if they have liberal or conservative interpretations of scripture and if they support free market ideologies. Catholics, along with many conservative Christian groups, are against population control. However, world population is expected to grow to at least nine billion people by 2050, and studies suggest that current global food production will need to double the 2010 output by the same year to meet growing global demand. This production will need to occur in a world undergoing anthropogenic climate change and suffering from loss of fresh water reserves. Some conservative evangelical groups, such as the Cornwall Alliance, believe in the power of human ingenuity and creativity and in free market economics and are confident that God's grace will allow for the suffering of humans throughout the globe who do not have from inadequate supplies of food and water to be alleviated. They are also supportive of using transgenic technologies to create nutrient and vitamin-enhanced food crops that can help provide what they perceive to be more nutritious foods to the millions around the world suffering from food poverty. This is just one of the many emerging Christian views on transgenic technologies, and prefaces debates to come in regard to this and the issue about human population size.

Summary

Overall, there are multiple Christian views from around the globe on food and agricultural ethics. It can be said with great confidence that there is an

articulate and theologically grounded view of food and agricultural ethics that has emerged in the last 30 years in regard to some parts of global Christianity that expresses concern for sustainable agriculture. Some of the key North American exemplars have been highlighted in this entry, but this is not to suggest that there are not leaders in other parts of the world acting in both institutional and personal settings. Future scholars of food issues will be helped by further research undertaken in both contemporary practices and theological understandings of food and agricultural issues, as well as in archival research, so scholars can obtain a better picture about Christianity's diverse historical relationship with food, agricultural ethics, and agricultural practices.

Introduction

This essay focuses on the uses of Christian stewardship in response to environmental concerns, especially in the field of agriculture in North America. The term stewardship means, at a basic level, responsible management of resources. This term has a tradition of use both among farmers and among Christians in North America.

The term stewardship is commonly used in farming circles to denote, at a minimum, responsible use of farming inputs, including fertilizer, herbicides, and pesticides, so that they are maximally effective, with few negative side effects. Stewardship in farming can, however, encompass much more. Practices of stewardship in farming that are more broadly focused attempt to take responsibility for the positive influence farmers can have on the wider ecological system, as well as the long-term health of their farms.

The term stewardship also has a history of use within Protestant denominations in North America. In this case the resources to be managed are primarily financial. Good stewardship within a congregation encourages donations and responsibly manages financial resources for the maintenance of the congregation and church mission work. Many Christians interested in responding to environmental concerns also applied it to mean responsible care for, and use of, creation, or management of natural resources.

The term in both of these Christian uses, as management of either financial or natural resources, stems from biblical stories of the role of a high-ranking servant, the steward, often given significant authority, who is responsible for the master's property. Especially in the case of care for creation, stewardship is also closely connected with key passages in Genesis. Stewardship thus combines a measure of power and humility, responsibility, and authority. The extent to which each element is weighted depends on the interpretation of the scriptures in question. The difference is often expressed by contrasting dominion with stewardship.

Many of the theorists discussed below emphasize the reverberations of Christian attitudes toward nature and land use into wider North American culture, from colonization to the present day. The

meaning and practice of stewardship in agriculture is closely tied to these Christian ideas.

Stewardship, with its roots in both farming culture and Christian tradition, seems a natural ethic for Christian farming. However, Christians do not agree on the meaning of stewardship, nor on what is demanded of farmers in applying the concept to contemporary farming. Thus, the multifaceted nature of “stewardship” presents challenges to Christian farmers who attempt to practice it on their farms.

Critics have further raised questions about whether a stewardship ethic can effectively moderate problematic aspects of industrial agriculture at all. Modern industrial agriculture places significant pressures on farmers to increase farm size and to specialize in intensively farming one or two commodities. These pressures often work against what is necessary for the best agricultural stewardship. For a stewardship ethic to remain effective, it requires practitioners to be motivated by values beyond economic returns, and for farmers to maintain a meaningful connection with the land and animals under their care.

This essay focuses on three areas. First, it examines contemporary Christian interpretations of stewardship, especially in relation to the environment. Emphasis on human dominion over nature is contrasted with human responsibility for earthkeeping, based on differing biblical interpretations. Next, the essay examines stewardship’s significance for farming. The farmer as gardener and caretaker connects with Christian images of the steward. Conflicts over agricultural land-use practices are closely connected with Christian debates on dominion and stewardship. Finally, it examines stewardship in the context of modern industrial agriculture. It considers whether a stewardship ethic, as part of an interconnected set of values, can effectively moderate or challenge the negative impacts of industrialization in agriculture.

Contemporary Christian Interpretations of Stewardship

The term “stewardship” is commonly used in North American Christianity. In his examination

of the steward as a Christian symbol, theologian Douglas John Hall points out that North American churches’ historical situation of disestablishment, that is to say, their lack of financial support through government, has meant that stewardship, especially of financial resources within congregations, has been vital to survival and prosperity (Hall 1990). The common use of the term stewardship in this context means raising and managing funds to sustain the life and mission work of the church.

More recently, the concept of stewardship has been broadened beyond just financial resource management to include care for the earth. With the rise in concern about environmental issues, the significance of the symbol has been expanded and has been applied in various ways to address relations between humanity and nature from within a Christian perspective.

While stewardship has significance beyond addressing environmental problems, it is also not the only way Christians have approached these problems. Christians have taken different approaches to interpreting Christian scriptures and traditions to better address environmental concerns. An ethic of stewardship has been an important part of this theological thinking and practice, but does not have universal appeal among Christians. For example, Laurel Kearns, in her sociological research into Christian environmental action, categorizes three types of environmental response among Christians in the United States, of which a stewardship ethic is just one, alongside ethics of eco-justice and creation spirituality. The stewardship ethic, she notes, has the greatest appeal among evangelical Christians (Kearns 1996).

To call humans “stewards” means that humanity has a special role in the care, preservation, and cultivation of nature. This role elevates humans, since the position of steward is one of authority and great responsibility. At the same time it maintains a sense of humility and submission to the greater rule of God, who is understood as the true owner and ruler of creation. Often this emphasis on the important role of humans as stewards is coupled with special concern for human health and benefits that result from proper care for nature.

The scriptural basis for the model of stewardship is very important for many Christians, both theologians and laypersons, who are invested in its potential as a model for guiding Christian behavior toward the environment. As noted above, its particular appeal among evangelicals explains some of this emphasis. As a result, much of the insider literature considers connection to and interpretations of scripture to better understand the relevance of the symbol and its potential for application to contemporary issues.

Christianity, especially in the West, has been accused of anthropocentrism, or excessive focus on the importance of humans. Most famously, this accusation came from historian Lynn White Jr. when he wrote that, "Christianity is the most anthropocentric religion the world has seen" (White 1967). This anthropocentric worldview, as White saw it, was based primarily in an understanding of humanity as created in God's image, and as being placed on earth to rule over nature, which existed for human benefit. This is the foundation of the idea of the dominion of humanity over nature, based on interpretations of especially Genesis 1:27–28, which reads, "So God created man in his own image, in the image of God created he him; male and female created he them. And God blessed them, and God said unto them, Be fruitful, and multiply, and replenish the earth and subdue it: and have dominion over the fish of the sea, and over the fowl of the air, and over every living thing that moveth upon the earth" (KJV). For many, these verses lay out at the very beginning the special relationship between God and humanity, who are in God's image, and the special role of humanity who are given dominion over nature.

Interpretations of the special place of humanity and the extent of human control over nature implied in the concept of stewardship vary. Some argue the role of human stewardship extends globally, over all living things and habitats. For them, stewardship is best realized through human control and development of nature, emphasizing the dominion of humanity over nature.

Others have used the model of the steward in responding to White's and others' accusations

that, especially in the West, dominion has been exercised excessively. They use later verses to give insight into their interpretation of the role humanity was given in these early Genesis passages and how dominion should be exercised. One such verse, often connected with the stewardship of nature, is Genesis 2:15 which reads "And the Lord God took the man, and put him into the garden of Eden to dress it and to keep it" (KJV). Writers such as theologian Loren Wilkinson and agronomist and practicing Christian Gary Fick argue that the true responsibility of Adam, who here represents humanity, is to be the gardener, the keeper, and protector of the earth (Wilkinson 1991; Fick 2008). Taking seriously the accusation that too often dominion was interpreted as domination, the use of stewardship here sees dominion not as a power given to humanity, but as a responsibility. Humans are to be good stewards of the earth, to tend and keep the earth on God's behalf. For Wilkinson, Fick, and others, a good steward is defined as a protector of creation.

Interestingly, neither steward nor stewardship is mentioned in either of these scripture passages. Instead, looking at the concept of the steward from both the Old and New Testaments, including later in Genesis, these passages are interpreted in light of their understanding of humanity's role as stewards under God's ultimate lordship.

For others, stewardship acknowledges and hopes to curtail the uncontrollable implications that human power has to disrupt nature, more than it calls on humans to exercise power as control, either in a dominion or keeping mode. As Robin Attfield, a philosopher of environment and religion, explains, "stewardship is not synonymous with interventionism, and is compatible with letting-be . . . [yet] responsibility remains possible for the entire sphere of nature which humans can affect. . . . Unless this extensive power is exercised with responsibility, global problems will be intensified. Thus the choice is between power exercised responsibly, and power without responsibility" (Attfield 2006). This is especially the case in agriculture, where human technology and practices in this field have wide-ranging effects globally.

Some, such as Hall, have gone beyond stewardship as management of either finances or human relations with nature. Hall argues that it has far greater potential. For him, stewardship is a symbol of human (Christian) vocation in the world, emphasizing that Christians should be engaged with the well-being of the material world. In his interpretation of the symbol, Christian stewardship would encompass work toward greater social justice, greater relations between humanity and nonhuman nature, and a more peaceful world (Hall 1990). Thus, the literature reflects a fairly broad spectrum of interpretation of what stewardship can mean in terms of human power and responsibility.

Stewardship's Significance for Farming

Just as stewardship is connected with the Christian experience in North America, it is also tied with the practice of farming. The influence of Christian attitudes to nature and land use is still apparent in conflicts within agriculture today. Despite the importance of the religious roots and use of stewardship, the term is used frequently by many outside theological circles, especially in reference to farming practices, often without any overtly religious meaning intended. Stewardship in this case often means good farm management. Michael Northcott, a Christian ethicist, points out that the term, in this more limited sense, is even used by agricultural input companies as well as by agricultural regulators (Northcott 2006).

Good stewardship in farming is commonly understood to mean practices that conserve and improve the health of the soil and protect the water and species of plants and animals that the farmer depends on to produce food and fiber for the whole community. A stewardly farmer is a good manager of the resources under her or his management, ensuring healthy farmland, adequate pure water, and healthy plants and animals. A good current crop must not come at the expense of lost soil, lost fertility, or contamination of the farm ecosystem in the long run. The symbol of the steward as gardener makes sense in a farming context. Thus, many see using the symbolism of

stewardship as particularly apt for approaching environmental issues related to farming practices.

Interpretations of dominion and the meaning of stewardship vary within an agricultural context as well and affect farmers' relationship with and treatment of their land. The issue of dominion is especially apparent in debates about property owners' rights. Farmers often now control large tracts of land on ever-growing farms. The implications of the practices of individual farmers on their own land, however, do not stop at their property lines and can affect those immediately surrounding the farm and also the wider ecology of the region. When taken together, common practices can have a global impact.

Frederick Kirschenmann, both a farmer and an agricultural academic, points out the sometimes-conflicting values on land use that Christians brought over into the "New World." On the one hand, they felt called to use and develop the land to its fullest potential (exercising dominion), and on the other hand, they felt called to preserve and protect the land as a place of freedom [and prosperity] for many generations (exercising stewardship). These values continue to conflict today, argues Kirschenmann, even within the same person. The contrast between these two values is sometimes expressed in the conflict between private property rights, or a sense of entitlement, and stewardship of the land, or a sense of greater responsibility to God or to future generations for the gift of land (Kirschenmann 2010).

Aldo Leopold also connected attitudes of dominion with emphasis on private property rights in his influential 1949 book *A Sand County Almanac*. Although Leopold was primarily concerned with conservation issues, much of what he has to say has relevance for agricultural issues related to the environment as well. He argued for what he called the land ethic, as a way to instill a deeper understanding of human responsibility to the wider community of soils, waters, plants, and animals, or collectively: the land (Leopold 1949). Leopold, as did White, explicitly connected attitudes of entitlement to ideas founded in interpretations of Genesis, but in Leopold's case he critiqued the stories of Abraham. Although these ideas have Christian

foundations, both argue that these attitudes now pervade Western secular culture and, in White's case, Western science and technology as well.

Stewardship is also tied to ownership of land, but in a different way. Paul Thompson, a philosopher of agricultural and environmental ethics, contends that stewardship in farming is primarily a selfishly motivated act (Thompson 1995). The farmer benefits directly from acting in a stewardly way. Farmers who own the land they farm logically have more incentive to look after their land. He or she has a greater investment in the long-term health of the soil and surrounding ecosystem, especially if the farmer has aspirations to pass the farm on to succeeding generations, as is the case with a family farm. This self-interest in the farming context moderates the sense of entitlement that also tends to accompany an understanding of private land ownership.

The public is coming to expect more from farms than just food and fiber. Farms now also produce other goods that are recognized by consumers such as environmental benefits, agritourism, and even energy production. Property rights are thus being balanced against wider social and environmental goods and the expectations of society at large.

The differences between dominion and keeping stewardship are evident within farming specifically. In his study of the use of stewardship among (especially Dutch) Christian farmers in Canada, geographer John Paterson makes a distinction between what he terms dominion stewardship and earthkeeping stewardship in farming. The differences in biblical interpretation discussed above are reflected in the emphasis of dominion stewardship on the entitlement of humanity from Genesis 1:28, while earthkeeping stewardship emphasizes the responsibility of humanity as keepers based on Genesis 2:15. Earthkeeping stewardship also gives greater emphasis to the intrinsic value of nature beyond human use and concern (Paterson 2003).

Stewardship in agriculture is primarily about sustainable use of nature. It is about managing certain areas of land and certain species of plants and animals in a way that provides a stable source of food and other benefits for humans. This can be

seen as both good and bad. Farmers are primarily concerned with preservation of soil and water resources, the basis of their livelihood, while (often urban) environmentalists may be primarily concerned with preservation of wild species habitat and pristine areas for conservation. Farmers argue that agriculture makes room for the needs of human beings as part of nature, while at the same time doing so with an awareness that a balance of give and take must be maintained. Environmentalists argue for the preservation of nature based on its intrinsic value or based on the recreational and aesthetic benefits it provides in a more pristine natural state.

Thompson points out that this apparent cross-purpose is founded in the religious notions of the role of humanity and the myth of the garden. If humans are primarily seen as gardeners of all of nature, as is sometimes the case in interpretations of stewardship, then the environmentalist agenda of preserving wild nature seems anathema (Thompson 1995). On the one hand, the gardener need not garden the whole of creation, as expressed in other interpretations of the term above. Yet some suggest they may go hand in hand. James Lovelock, an independent scientist famous for his work on Gaia Theory which postulates the earth as a self-regulating system, argues that more intensive farming methods allow greater production from smaller areas of land, making it possible to "leave alone" larger areas for conservation purposes (Lovelock 2006a).

The idea or symbol of stewardship has the ability to narrow and widen like the aperture of a camera lens. Different interpretations expand or contract the privileges or responsibilities implied in the concept. Does good stewardship simply entail following the best practice recommendations of the input companies, or is it saying something much more profound about the value of all life on earth? Critics and proponents of stewardship often have differing views on its narrowness or breadth. Proponents such as Hall see it as having a broad significance and as inhabiting important middle ground between excessive control and slothful apathy (Hall 1990). Opponents of stewardship instead accuse it of being too far toward the side of excessive control, as being

too utilitarian, and not sufficiently recognizing the intrinsic value of all life.

Critics of stewardship, such as Thompson or Lovelock, tend to take more narrow interpretations of the types of demands stewardship places on the human practitioner. Thompson accuses stewardship of being excessively human-focused, saying “agricultural stewardship is entirely compatible with self-interested, anthropocentric use of nature” (Thompson 1995). Lovelock compares stewardship to imperialism, with hubris and nemesis soon to follow (Lovelock 2006b). As shown above, these accusations are a good description of interpretations of the term that emphasize human control over and development of nature. However, these criticisms do not address the full breadth given to the term by those, including Attfield, Hall, Fick, and Wilkinson (mentioned above), who use stewardship to mean earthkeeping or even a greater responsibility for the potential impact of human activity on nonhuman life.

Stewardship in the Context of Modern Industrial Agriculture

Stewardship practices face new challenges within the context of modern industrial agriculture. Some are concerned about the negative impacts of changes in farming, considering that the population of farmers is both aging and shrinking in numbers. Farms are growing bigger and bigger, as farming equipment allows one farmer to manage ever-increasing acreage, flocks, and herds (Kirschenmann 2010). Farmers must navigate storms of weather as well as of the economy and politics. Interest rates can be as devastating to farming as lack of rain in a system that now heavily relies on expensive inputs and technology. The ability, or lack thereof, to implement stewardly practices is often at least partly determined by economic factors. Sometimes even the self-serving aspect of stewardship is not enough incentive in the face of other pressures on farmers.

Although economic factors are important, writers such as White and Leopold illustrate that worldviews are also important determining

factors in how farmers treat their land. White argued that Western Christian anthropocentric attitudes were and are expressed in forceful and controlling farming technology and methods (White 1967). Leopold says in the conclusion of his essay “The Land Ethic” that, “[t]he bulk of all land relations hinges on investments of time, forethought, skill, and faith rather than on investments of cash. As a land-user thinketh, so is he” (Leopold 1949). Both of these writers caution that underlying human attitudes toward the land will have far reaching effects on the treatment of it.

So long as farming methods allow farmers to maintain a direct connection with the landscape, soil, plants, and animals they farm, they can still invest time and thought into meaningful stewardship practices. It is the quality of this connection with “the land” that is important in determining the extent and effectiveness of the stewardship that can be accomplished. Through modern industrial agriculture, humanity has ever-increasing control over aspects of farming that were uncontrollable in the past. New technologies and farm efficiencies result in bigger crop yields per acre, greater dairy production per animal, and animals that fatten more quickly than ever before. As farming increases in scale and intensification, so too do the uncontrolled risks farming poses to humans and other surrounding species. With the increasing industrialization of farming, the relationships between farmers and the land change, as well as the relationships between farmers and eaters and among rural and urban communities. The wider consequences of new farming technologies may not be immediately apparent.

Some critics of industrial agriculture point in particular to the social impacts of the changing size of farms on rural communities. Wendell Berry, an influential agrarian thinker and essayist, who is himself both a Christian and a farmer, has offered many criticisms of the effects of industrialization on agriculture and on society at large. Berry’s critiques extend to both the impacts of changing technology on rural life, and also the wider social impacts this has on moral character, and on community life in general. Specialization and industrialization fundamentally change

human relationships to land, work, home, and community. Losses and changes previously experienced only in urban areas have now come to the farm as well.

Industrial agriculture has also shifted the primary sources and uses of energy on the farm. Berry contrasts energy from the sun, which can be used cyclically, with energy and nutrients from fossil fuels, which must be used wastefully (Berry 1977). For Berry, the sustainability of any technology that continues to use and depend on wasteful use of limited sources of energy and nutrients is in question. Environmental concerns are too much ignored in an industrial ideal that pushes aside a large part of the human and animal population whose labor and livelihood is replaced with increasingly powerful machines. Where animals and humans can work on cyclical energy sources, returning fertility to the land, machines are dependent on petroleum not only to fuel the tractors but also to feed the soil as fertilizer.

Berry argues that an ethic of stewardship, in short, does not stand by itself. It is a value expressed alongside values for community, industriousness, and even to some degree self-sufficiency (Berry 1977). As stewardship is primarily a question of balance, it raises the issue of limits, and of the effects of size and scale, as much as of kind. It is best practiced, Berry argues, when technology and economy remain at a “human” level, allowing the farmer close enough connection and familiarity with both the land he or she farms and the community in which he or she lives to be effectively responsible to both.

Writers such as Barbara Kingsolver, a novelist and nonfiction writer, and Mark Graham, a Christian theologian and ethicist, join Berry in reflecting on the connected problems of intensification and expansion, mechanization, and diminishing rural community life. They have each looked for examples that illustrate effective alternatives that manage to keep the interconnected values mentioned above in balance. Traditional Amish and Mennonite farming communities form examples that all three look to as effective alternatives to modern agricultural methods (Berry 1987; Graham 2005; Kingsolver 2007). These communities farm with methods and

technologies that still make effective use of cyclical energy sources, and they maintain the importance of community, family, hard work, as well as stewardship over the long-term. More moderate challenges to the forces of industrialization are also evident in other Christian farming communities, who also value the importance of community and stewardship, as research into Dutch-Canadian farmers in central Canada attests (Paterson 2001).

The importance of the “family farm” is related to concerns about the effects of technology and economic forces on these connected values in farming. Some in the farming community argue that farming methods that still remain at the level of management of a “family farming business” should be able to sustain the values of family, community, and stewardship. It is when farming moves to a different model of labor and capital that it fundamentally changes, and with it, the possibility for quality stewardship changes also.

One figure that has emerged as a vocal spokesperson for alternative farming methods and the importance of stewardship in farming is Joel Salatin. Made famous by Pollan’s 2006 book *The Omnivore’s Dilemma*, he is both a practicing farmer and inspirational speaker. He often makes connections between his religious worldviews and his particular farming and stewardship practices. Salatin’s farming philosophies are an eclectic mix, which often bridge concerns shared by environmentalists and farmers, urbanites and rural people, and evangelical Christian and New Age perspectives on environment. While clear divides exist between many of these groups, he illustrates that points of connection can be found.

Humans need to find a balanced and meaningful relationship with nature to survive and thrive into the future. Berry contrasts the technological ideal of industrial farming, (which could be extended to industry of all kinds), with the ideal of preservation environmentalists. Neither, he believes, see a meaningful role for humanity. “Neither the agricultural specialist nor the conservation specialist has any idea where people belong in the order of things. Neither can conceive of a domesticated or humane landscape. People . . . are perceived by the specialist as a kind of litter,

pollutants of pure nature on the one hand, and of pure technology, total control, on the other” (Berry 1977). Writers such as Hall and Berry seek a middle ground, a meaningful place for humans in a balanced relationship with nature. What that means in practice is what is at issue.

Summary

Environmental stewardship is about the relationship between humanity and nature. Those seeking a stewardship model in agriculture see the need for healthy human culture as well as a healthy natural environment, where both can work together in meaningful and reciprocally beneficial ways. Christian stewardship in agriculture is interpreted in different ways, giving it different scope and emphasis. With connections to passages in Genesis, a stewardship view includes some notion of the human as gardener, or farmer. It is not about letting nature completely alone, nor about excessive control of nature through technology, but about meaningful and balanced relations between humans and nonhuman nature.

Christianity and Food

David Grumett

School of Divinity, University of Edinburgh, New College, Edinburgh, UK

Introduction

Food preparation, cooking, and eating are regulated less formally in Christianity than in other religions, such as Judaism and Islam. Although it is not always possible to identify Christian ethical rules governing specific procedures and practices, teaching and wisdom offer extensive general guidance. Key sources include scripture, tradition, and monastic rules. In this contribution, Christian teaching will first be situated in the context of the imperatives of the Old and New Testaments. The Christian preference for simple diet and preparatory methods will then be discussed, followed by the high valuation of the task of cooking in monastic rules and Christian influences on specific dietary options and recipes. Finally, the ways in which flexibility and rules have each played a part in shaping the choices of Christian diners will be considered.

The Two Testaments: Change and Continuity

In the Christian communities of the New Testament, the status of the Jewish law, received from God by Moses, was debated extensively. In this law, rules governing food preparation were prominent. This debate became heated as Paul's mission to the Gentiles began. (Gentiles were non-Jews who had not previously followed the Jewish law.) Jesus' teaching seemed to suggest that some parts of that law no longer applied or did not apply to the Gentiles (Matthew 11.25–30, 23.13–28; Mark 7.14–23; Luke 10.29–37, 18.9–14, John 1.14–18). Yet Jesus also presented himself as not abolishing the Jewish law but fulfilling it (Matthew 15.17–20, Luke 16.16–18, John 5.45–7). In view of this apparently contradictory teaching, did Gentile converts to Christianity need to observe the full

requirements of the Mosaic law relating to food preparation, especially as laid down in the Old Testament books Leviticus and Deuteronomy? At the Council of Jerusalem, a compromise was reached in which all Christians were urged to abstain from food sacrificed to idols, from blood, and from the flesh of living beings killed by strangulation (Acts 15.29). Christians were therefore expected to continue some Jewish meat preparation practices. Other Jewish customs could, by implication, be discontinued, such as the requirement not to mix milk and meat (Exodus 23.19b).

Isolated attempts have been made to reinstitute aspects of the Mosaic law relating to food preparation, notably in Celtic Ireland in the seventh through ninth centuries and in other regions under the influence of Eastern Orthodox Christian missions (Grumett 2008). Yet in subsequent Christian history, even the minimal expectations articulated at the Jerusalem Council were mostly ignored. Nevertheless, a significant strand of teaching censures elaborate methods of food preparation and cooking, associating these with the sin of gluttony and urging Christians to adopt simple methods. The classic understanding of gluttony encompassed a considerably wider range of activities than is generally assumed today (Miller 1997). Gluttony was not simply, nor even primarily, the sin of consuming excessive quantities of food. As Thomas Aquinas (1962–1976) taught, gluttony included the sin of eating food that was too costly or difficult to prepare as well as the sin of eating too early or too quickly (*Summa theologiae* II.2, q. 148, a. 4, resp.).

A Simple Diet

In his fourth-century monastic teaching, Basil of Caesarea promotes a simple diet employing ingredients that are available locally. He counsels:

We ought to choose for our own use whatever is more easily and cheaply obtained in each locality and available for common use and bring in from a distance only those things which are more necessary for life, such as oil and the like or if something is appropriate for the necessary relief of the sick – yet even this only if it can be obtained without fuss and disturbance and distraction. (*Longer Responses* 19)

Basil here recognizes that, in monasteries, gluttony could become an acute temptation. Although monasteries were traditionally strictly ascetic, economies of scale made it possible for their members to obtain foods and employ preparation methods unavailable to the wider populace.

Christians have promoted simplicity in cooking as well as in food sourcing and preparation, with ascetics subverting the traditional hierarchy described by Claude Lévi-Strauss (1969) that assigns cooked food a higher status than raw food (Twigg 1979, 1983). The desert fathers were noteworthy in this regard. These hermits lived apart from society in the early centuries of Christianity in order to pursue a life of prayer and self-denial. In their *Lives* (1981), the desert fathers are presented as subsisting on very small quantities of roots, leaves, herbs, pulses, seeds, and olives. In Palestine and Syria an especially strict group, known as “grazers,” ate only grass, sometimes alongside wild animals. Most of these simple foods have been classed by humoral theorists like Aristotle, Galen, and Albert the Great as “cold” and “dry,” in contrast with the “hot” and “moist” dishes that would typically be produced through cookery. “Hot” and “moist” dishes, especially cooked meat, were seen as warming the body and leading it into temptations, above all sexual temptations, whereas “cold” and “dry” foods, such as raw vegetables, were believed to maintain the body in a state of physical purity and spiritual discipline.

These theories were promoted by many early Christian authorities such as Jerome and Basil of Ancyra. They were revived by nineteenth-century health reformers, many of whom were prominent Christians. In 1829, Dr. Sylvester Graham, the Presbyterian minister and temperance lecturer, invented the cracker biscuit that bore his name. This tasted like a digestive biscuit and had a similar consistency as well as a dryness intended to curb sexual urges. At the start of the twentieth century, the Kellogg brothers and other Christian entrepreneurs pioneered breakfast cereals and other meat substitutes such as peanut butter in order to wean Americans off their pork, beans, and pie breakfasts (Carson 1959). John Harvey Kellogg and William Keith Kellogg were Seventh

Day Adventists based at the church’s Battle Creek Sanatorium in Michigan. The Christian context of some breakfast products was proclaimed by their names, which included Food of Eden, Golden Manna, and even Elijah’s Manna. Today breakfast remains the daily meal most deeply impacted by Christian dietary ideals, in both its generally raw ingredients and simple preparation.

Although mainstream Christianity has obviously not viewed all cooking negatively, a concern to avoid unnecessary cooking has persisted. This is well expressed by Clement of Alexandria (1993), who in his *Instructor*, written around 200, commends “simple, truly plain” food that ministers to “life, not to luxury” (ch. 2.i). Such food, he continues, is “conducive both to digestion and lightness of body, from which come growth, and health, and right strength.” Clement attacks a range of elaborate food preparation methods, including pastry making, and condemns consumers of elaborate dishes as “gluttons, surrounded with the sound of hissing frying pans” who wear their “whole life away at the pestle and mortar.” These comments indicate that, if raw items are edible and in sufficient supply, they should be preferred to cooked dishes.

One of Clement’s complaints is against cooks who “emasculate plain food, namely bread, by straining off the nourishing part of the grain, so that the necessary part of food becomes matter of reproach to luxury.” This critique of white bread re-emerged in the nineteenth-century health reform movement. Sylvester Graham, previously mentioned, regarded white bread as nutritionally deficient, promoting in its place brown bread made with his own brand of wholemeal flour, which contained coarsely ground bran and germ. By commercial means such as these, theological choices about recipes and preparation methods made wide impact on daily life, with products marketed as part of an embodied spiritual discipline. Bodily health was widely viewed as indicative of spiritual health and even of personal salvation.

The criticisms of early Christian writers and later Christian health reformers were directed primarily against meat (Grumett and Muers 2010), which usually had to be cooked before it could be

eaten. Part of the reason that cooking could historically be regarded as a superfluous activity was that levels of meat eating were generally low, certainly compared with current levels in the West. Yet beyond monastery walls, abstinence from meat was not the norm at all times. Feasts marked important points in the Christian year, especially Easter and Christmas, and good cooking, including meat dishes, helped make them special. Indeed, Jesus himself cooked and ate fish after his Resurrection, in the presence of several disciples (John 21.9–13). This suggests that cooking should in principle be viewed positively, providing its results are not unnecessarily luxurious nor the preparation process needlessly time-consuming.

Cooking and Recipes

In the rules of some monastic communities, cooking is regarded as a sacred commission. In the *Rule of Benedict* (1989), composed around 540, the cellarer, who functioned similarly to a bursar, is exhorted to “look upon all the utensils of the monastery and its whole property as upon the sacred vessels of the altar” (ch. 31). This ethic of culinary care is confirmed in the eighth-century *Longer Rule for Canons* composed by Chrodegang of Metz (2005), in which the cooks are to be “selected from the most faithful members of the household of the church, and be carefully trained to their work, so that they may be capable of attending to the needs of the brethren appropriately, both by their skill at cooking and by their pure faith” (ch. 11).

This view of cooking as a sacred charge is clearest in some of the practices surrounding the manufacture of the leavened bread used in the Eucharist. In many ancient traditions this bread was required to be prepared in silence, or by priests, or while specific psalms were chanted, or while special clothing was worn (Galavaris 1970). In some places the bread had to be baked in church, in an oven provided for this purpose. In any case, the bread was expected to be of high quality, made with finely ground sifted flour, and usually had to be baked on the day on which it was

offered. In his *Lausiac History* (1918), Palladius describes the hermit Candida rising at night to grind corn, light the oven, and bake the loaf for the morning Eucharist (ch. 57). The leaven, which was reserved from the previous batch of dough, was seen as testament to a church’s continuing eucharistic tradition. In some churches it was even traced back to a portion associated with Jesus or one of his apostles.

The seasonal prohibitions of specific food-stuffs discussed earlier have influenced the development of recipes that remain popular today. The most important such season has been Lent, lasting about six weeks, when red meat, poultry, dairy products, and eggs were historically banned by both church and state (Henisch 1976). Pancakes and recipes involving the frying or roasting of pieces of meat are made in many countries during Shrovetide or Carnival, the period immediately before the start of Lent. Although Mothering Sunday, which falls around the middle of Lent, was a time for relaxation and family gatherings, food prohibitions nevertheless continued. To provide a suitable treat without employing any banned ingredients, dried fruit and nuts could be used with marzipan (made from almonds, the standard milk substitute), yeast, and saffron to produce simnel cake. Hot cross buns were baked on Good Friday, although after the Reformation Protestants viewed these with suspicion because of their associations with the eucharistic bread, which Catholics reserved on the previous day. Easter eggs, which originally were hardboiled decorated eggs, were exchanged at the end of Lent. This was because, once the ban on egg consumption ended, they were available in abundance.

Fish cookery has been indirectly promoted by Christian bans on the consumption of red meat that applied across society during Lent and on regular days of abstinence such as Fridays, as well as throughout the year in most medieval monasteries (Grumett 2011). These monasteries were well known for their lavish fish cookery and frequently criticized for it by those who viewed such cookery as incompatible with the spirit of monastic simplicity. The custom of serving fish on Fridays continues today in many restaurants and refectories.

Medieval monasteries also played an important role in brewing, winemaking, and the distillation of spirits, as evidenced today by the names of many alcoholic drinks and producers. Alcohol, unlike meat, was not banned in monasteries. Although John Wesley, who founded Methodism, condemned distilled spirits, general prohibitions of alcohol under Christian influence were rare before the temperance movement of the later nineteenth century (Fuller 1996).

Eating: Flexibility, Rules, and Choices

Meals comprise a central strand of the biblical narrative about Jesus. It is notable that a meal, the Last Supper, is Jesus' final act of fellowship with his disciples. All four Gospels include an account of Jesus presiding at this meal (Matthew 26.20–9, Mark 14.17–25, Luke 22.14–38, John 13.2b–17.26). In John's account, moreover, this meal is an occasion when Jesus tells his disciples much about himself and his destiny. In Luke's Gospel, furthermore, after his Resurrection Jesus reveals himself to some of his disciples in the breaking of bread (24.30–1). (This breaking was the prerogative of the host and a standard part of any meal.) Paul provides the first account of a Christian Eucharist, presenting it as a memorial and proclamation of Jesus at which bread and wine are consumed (1 Corinthians 11.23–6).

Jesus was a guest at many meals in the course of his ministry and was frequently criticized for accepting invitations to the tables of tax collectors and sinners (e.g., Matthew 11.19). His example promotes a flexible approach to dining and is developed by Paul (Romans 14.1–15.13; 1 Corinthians 8–11.1). For the reasons discussed at the beginning of this entry, however, flexibility did not entail complete liberty. Rather, Paul taught that choices about accepting hospitality and the foods offered should be made with a view to the effects of those choices on other people, whether Christians, Jews, or Gentiles, and on the Christian mission. For instance, unrestricted consumption would likely offend potential Jewish converts, just as excessive strictness might deter Gentiles. A well-known figure from much later in Christian

history, who acted similarly to Jesus, is Francis of Assisi, who in 1210 founded the Franciscan order. Although Francis' preference was to avoid meat, he was not completely vegetarian, because this would have impeded his ability to share the life of the people around him. This included being a guest at meals, at which meat would sometimes be served (Grumett 2007).

The Gospels recount many shared meals, and dining together in a single room became the norm in monastic communities, as reflected in their written rules. In the *Rules of Pachomian* (1981), composed in about 320, special care is taken to prevent eating in any other location. It is stipulated that no food be taken from the community's garden, fields, or orchard for personal consumption nor stored privately (chs 71–80). These rules applied even to windfall fruit. From then onwards, monasteries had a refectory in which meals would be taken in common and in which the dining rules were enforced. As monasteries grew larger, however, other dining areas were created in which the rules were deemed either not to apply or to apply less strictly.

At least as significant as the location in which meals were taken was the time of eating. In the fifth-century *Rule of Saint Augustine* (1984), adopted by the Dominican order, the main meal was delayed until late in the afternoon, although monks and nuns who were unable to fast for that long were permitted to take some food around midday (ch. 3.1). In the later *Rule of Benedict*, the time of the main meal, which was the first meal of the day, varied according to the season. For example, during Eastertide it was taken at midday ("the sixth hour") and followed by supper, whereas in the penitential season of Lent, it was delayed until evening (ch. 41). On most other days it could be taken at around 3 p.m. ("the ninth hour"). The principle of delaying the first and often only meal of the day in order to fast was a standard monastic discipline, but in recent decades has found very few advocates (although see De Vogüé 1989).

In monasteries and convents, although dining was communal, speaking during meals was prohibited. Requests for food or utensils were communicated via a simple system of sign language

(Ambrose 2006). At some meals, diners listened to readings from scripture or other edifying texts or to extracts from their rule. This left them free to meditate and eat their food thankfully.

Even in the relatively strict monastic dining context, a choice of dishes was permitted. The *Rule of Benedict* allowed monks to choose between “two cooked dishes, on account of individual infirmities, so that he who perchance cannot eat of the one, may make his meal of the other” (ch. 39). The *Rule of the Master* (1977), compiled shortly before that of Benedict, unusually allowed meat to be eaten at the Easter and Christmas feasts by those who wished. But this choice was presented in such a way as to discourage the meat option. The rule states:

Let those brethren of a deanery who are going to eat meat be seated beside one another at their own tables, and let the specially cooked meat courses be brought to them in separate dishes, lest the purity of the abstainers seem to be sullied, and in order that the eaters may notice how great the distance is between them, those who cater to their desires and those who master the stomach. (ch. 53)

Moreover, the Master advises in the same chapter that, when the feast approaches, the monks be guided in their choice and encouraged to join the abstainers’ table.

In the later medieval period, monastic gluttony was frequently the object of wider public critique. Interestingly, similar criticisms of conventual practice are much rarer, suggesting that nuns were more likely to observe the spirit of their rule than monks. In Geoffrey Chaucer’s *Canterbury Tales*, which were written in the late fourteenth century, for example, the monk’s favorite meat is roasted swan, suggestive of lavish expense as well as pride and sloth, while the summoner (a friar) enjoys garlic, onion, and leeks, which were often believed to possess aphrodisiacal properties. The good widow of the *Nun’s Priest’s Tale*, in contrast, lives simply, drinking no wine and eating milk and brown bread (Biebel 1998).

It is significant that the decline in monastic dietary discipline was associated with a move away from common dining in a single place at a fixed time. In the modern world, traditions of common family dining are threatened by the

rapid spread of mass fast food culture (Grumett et al. 2011). Yet from the perspective of a Judeo-Christian theology of creation, food is a gift from God to humankind that is, as such, given within boundaries and with limitations (Genesis 1.29). A misplaced desire to consume food and to have food accepted by God lies at the root of the two great primordial biblical sins: the expulsion of Adam and Eve from Eden after they tasted the forbidden fruit (Genesis 3) and the murder of Abel by his brother Cain after God’s rejection of the latter’s vegetal offering (Genesis 4.1–16). This sinful nexus of consumption, estrangement, and annihilation contrasts starkly with the Sabbath rest into which God calls all people (Exodus 20.8–11), in which waiting and the taking of time allow lives to be shaped by principles other than consumption.

Conclusion

Although the expectations surrounding food preparation, cookery, and eating are less clearly codified in Christianity than in many other religions, traditions of practice and interpretation with ethical relevance can nonetheless be identified. These emerge from Old Testament legislation, its interpretation in light of the teaching of Jesus, and the subsequent codification of both by churches and monastic founders. The ingredients and preparation techniques employed should both be simple. For this reason, local sourcing of ingredients is desirable and foodstuffs that may be eaten raw should normally be preferred where practicable, as part of a balanced diet suitable for the individual. Moreover, particular seasons and days of abstinence are part of Christian tradition. Preparing the dishes associated with them is one way of engaging present-day Christians with the dietary history of their faith and, via that history, with their faith’s cycle of feasts and fasts, its scripture, and its doctrines.

Such principles have wider relevance. The renewal of interest in monastic wisdom and mindful practice that is evident beyond the boundaries of institutional Christianity suggests that Christian traditions of food preparation, cooking, and eating have continued relevance for wider society.

Indeed, by giving such features of their religion greater prominence, Christians might demonstrate a more embodied and rooted faith that appeals to people who are currently searching for enlightenment elsewhere.

Introduction

Civic agriculture is a term used to describe several alternative forms of farm-based entrepreneurship which emphasize the embeddedness of agricultural activity in local communities. Embedded local agriculture is characterized by direct linkages between producers and consumers, thus forging tighter relationships in communities and creating a multiplier effect in local economies. Civic agriculture emerged as a discursive frame in rural sociology, geography, and development studies with the publication of a series of articles and texts by Thomas Lyson and others in the late 1990s and early 2000s (Lyson 2000). Civic agriculture developed among other theoretical and descriptive frames, such as alternative food networks, as a response to the relative lack of attention given to how and why small-scale producers persisted through the agricultural restructuring in the United States in the 1970s and 1980s. Lyson (2004) writes that civic agriculture is thought to “fill the geographic and economic spaces that have been passed over or ignored by large-scale industrial producers” (p. 61).

The proliferation of local food systems in the past several decades constitutes key points of diversity and resistance in the agricultural economy that, according to “civic agriculture” explanations, signals a shift toward a more public agriculture. While diverse, these socioeconomic activities in agriculture have in common, according to Lyson (2004), the potential to

“nurture local economic development, maintain diversity and quality in products and provide forums where producers and consumers can come together to solidify bonds of community” (p. 87). In what follows, this entry will provide some elaboration of the key principles and concepts of civic agriculture. Of particular interest to scholars studying civic agriculture are the ideas of embeddedness, public goods, and community development. The entry will conclude with capturing some of the debates around justice, gender, and postcapitalist politics that are often overlooked in theories of civic agriculture.

Civic Agriculture

Conventional, industrial-scale agriculture produces cheap food and fungible commodities as well as well-documented social, economic, and environmental problems. Consumers of conventional foods are generally separated socially and geographically from the places of food and commodity production, keeping them ignorant of and disconnected from production practices. Civic agriculture is characterized by complementary social and economic strategies that are intended to provide economic benefits to farmers as well as socio-environmental benefits to the community. These benefits can include cleaner water through reduced chemical use, fresher food through direct marketing, and closer relations between producers and consumers through short supply chains. Through cultivating a sense of loyalty to agriculture’s limits and capacities in a particular place, civic agriculture aims to develop a kind of “food citizenship” (Lyson 2005).

Civic agriculture differs from other technical innovations in agriculture emerging around the same time, such as certified organic production, in the way that issues of social welfare are emphasized. Technical practices often overlook, or are not designed to accommodate the social dimensions of equity in the food system. The advocates for social welfare in the food system call for the long-term maintenance of farming livelihoods, the provision of quality food and nutrition to individuals regardless of socioeconomic status,

and the distribution of public goods (i.e., clean water or living wages) throughout a community. Lyson (2004) suggests that a more “civic” agriculture draws on notions of economy that incorporate social relations, cultural and environmental history, and local politics into agricultural production and distribution. Small-scale farmers aim to increase “community capital” by contributing directly to the local economy and to the social and physical health of local residents. The civic agriculture approach highlights the “problem-solving capacity” (Lyson 2004, p. 63) of locally organized food systems, which are “characterized by networks of producers who are bound together by place” (Lyson 2005, p. 92).

Lyson (2004) developed his theory of civic agriculture by examining in detail several studies on small businesses commissioned by the Congress in 1946. These studies, conducted by sociologists Mills and Ulmer and anthropologist Goldschmidt, compared communities on the basis of well-being related to the presence or absence of small-scale businesses and large-scale agriculture, respectively. They found that communities with more small businesses and small-scale farms scored higher on quality of life measures. While the results of these studies did not change the trajectory of American agriculture and rural communities at the time, Lyson uses them to articulate the characteristics of the small-scale business enterprises that survived the modernization of agriculture. They are summarized as follows: (1) selling in local markets, (2) integrating agriculture into the community, (3) producing value-added and quality products, (4) staying small-scale and land- and labor-intensive, (5) using site-specific knowledge, and (6) maintaining short supply chains.

The benefits to community welfare are clearly greater than the sum of these characteristic parts, as any given small business could diminish public health or degrade the environment with its practices. Civic agriculture thus distinguishes itself not just in its scale, scope, or supply chain but in what Lyson (2004) identified as contributing to the “problem-solving capacity” of communities. By this he refers to the inclusion of community welfare as a factor in business decision-making,

rather than simply pursuing profit at the expense of social welfare. By promoting a wider community welfare, “food citizens” participate in activities that contribute socio-ecological benefits (Wilkins 2004, p. 269). The characteristics of activities that make these kinds of contributions are threefold. The first of these characteristics is their embeddedness in local communities, the second is the production of public goods in addition to the production of farm products, and the third is the facilitation of community economic development.

Embeddedness

Civic agriculture, as an alternative form of entrepreneurship, emphasizes local food systems as a livelihood strategy. These are locality-based markets established through direct sales to consumers. Examples include community gardens, farmer’s markets, community-supported agriculture (CSA), box schemes, and preordered and bulk meat purchases, among many other innovative production and distribution strategies (Lyson 2004). These strategies are designed to promote community social and economic development in ways that commodity agriculture, which participates in global-scale markets, does not (Lyson and Guptill 2004). Civic agriculture accomplishes this through economic short supply chains premised on trust, transparency, and reciprocity. Because of the multiplier effect of local economies, the kinds of enterprises that are most likely to promote economic development are those that connect producers and consumers through direct marketing or locality-based food processing and procurement.

Public Goods

According to Wright (2006), civic agriculture “exists *between* market and society” (p. 226, emphasis in original) and incorporates social welfare into its bottom line. As such, civic agriculture lends itself well to the embedding of social needs into economic activities of localities (DeLind 2002). In other words, civic agriculture connects

farming and its benefits to a place and its residents, rather than externalizing them. For example, in Trauger et al. (2010), women farmers in Pennsylvania used the farm as a site to produce food, but also to meet social needs, such as safe after-school spaces for rural at-risk youth or as a site for the production and processing of Halal meat for immigrants in the community. Most farmers in the study also provided public education through direct physical engagement with the practice of farming. This is part of what DeLind (2002) calls civic agriculture's "purposeful and enlightening public obligation" (p. 219).

Community Development

Civic agricultural enterprises contribute to community public goods by promoting "agricultural literacy" through cultivating place-specific knowledges (DeLind 2002). For example, Saldivar-Tanaka and Krasny (2004) suggest that urban gardens in Latino communities function as critical sites of education, empowerment, and community participation. They identify the garden as a "participatory landscape" which provides critical connections to heritages lost through immigration, and this function is perhaps more important than its role as a site of food production. Another way civic agriculture promotes community development (and meets social needs) is through farm-to-school (FTS) initiatives, which are increasing in popularity in many urban and some rural communities. The high obesity rate among youth is an increasingly prevalent problem, and the poor food environments of public schools are implicated in this trend. Bagdonis et al. (2009) studied FTS projects in Pennsylvania to determine whether and how the community problem-solving dimensions of civic agriculture can contribute to successful FTS programs.

Civic Agriculture Debates

In positioning civic agriculture in opposition to (or at least the opposite of) industrial agriculture, theories of civic agriculture establish an unhelpful

binary, in which civic agriculture is good and industrial agriculture is bad. Thus, a central criticism of civic agriculture revolves around the way certain aspects of it have been idealized. A common criticism of civic agriculture is the way it normalizes market relations and overlooks the inequities inherent to capitalism. Thus, justice issues rise to the fore in criticism of civic agriculture, especially with regard to the social, economic, and geographic marginalization that many farmers face. Related to this, civic agriculture also normalizes the social relations at the household scale in small-scale family farming models. Research investigating gender relations in civic agriculture indicates that family farming may not be the only avenue toward producing public goods via agriculture.

Market Relations

DeLind (2002) cautions against conflating local agriculture with a universal public good, especially considering that production and consumption of local food still contribute to capitalist social relations. Hinrichs (2007) distinguishes between approaches that emphasize opposition and "defensive localism" and those that emphasize "civic renewal and redemocratization" (p. 6). Similarly, DeLind argues that (2002) local food systems cannot simply pursue alternative marketing strategies to be civic. In her view, civic agriculture must be "embodied" or material and explicitly "public" or collective. DeLind (2006) argues that agricultural activity in public spaces can foster "soil citizenship" where community members can have a stake and role in meeting social needs through agriculture. The material benefits and consequences of civic agriculture are a product of the physical work of farmers and material exchanges between farmers and consumers. As such, simply buying and selling food in a local market is not enough. A mutual stake in the risks and costs of production, through, for example, a work share in a CSA, is required for agriculture to be truly "civic." Given this criticism, theories of civic agriculture may need to incorporate some of the discourse of food

sovereignty into its framework, which explicitly call for the transformation of social relations.

Justice Issues

Simply connecting producers to consumers in direct marketing relationships does not automatically create a wider public good, and many are concerned about the implications of equating production and consumption with citizenship. Hinrichs (2000) points out that power and privilege are not evenly distributed in the locality-based food systems and there are power- and class-based inequities in local food systems between consumers and producers. Brodt et al. (2006) further suggest that while some farmers are actively engaged in community development, many sustainable and conventional farmers are socially and geographically marginalized in their communities. Thus, civic agriculture needs to consider the implications of suggesting that all industrial-scale businesses do not contribute to a wider public good and perhaps expand or revise the definition of civic agriculture to more accurately capture the unique contributions of some small-scale businesses. It is also necessary to consider that relatively less affluent and time-poor small-scale producers may have their own quality of life decreased in the pursuit of the public good for others.

Gender Relations

Many of the institutions promoting agriculture continue to adhere to the agrarian ideal of family farming, which assumes rather rigid gendered divisions of labor and decision-making on the farm. Thus, many farm women identify themselves, and others commonly associate them, with social reproductive (versus economically productive) roles. Civic agriculture, according to Lyson (2004), is also similarly laudatory of small-scale family-based business models without paying any explicit attention to gender or the roles of women. Research on civic agriculture models, however, suggests that women farmers, when the sole operator or business partner in a farming operation, tend to support and

develop enterprises exhibiting civic agriculture characteristics (Trauger et al. 2010). This research shows that the marginalization that women farmers face and their socialization into caregiving roles in rural communities may actually contribute to their community conscience and desire to contribute to the problem-solving capacities of their community. Thus, theories of civic agriculture need to take into account the household-scale dynamics of the kinds of small farm business it tends to promote.

Future Research Directions

While civic agriculture narratives are clear in their criticism and the discursive construction of solutions to the problems in local food systems, less clear in these accounts are the actual processes required to create interdependence within communities and generate public goods through agriculture. A problem with theories of civic agriculture lies in identifying the specific mechanisms through which these benefits can be produced, and how characteristics of the farmers themselves (such as gender) can condition the production of benefits. Additionally, civic agriculture tends to see state or capital as driving problems in the food system, either through federal policy or global markets or some combination of the two. Thus, productive new arenas for research on civic agriculture may incorporate contributions from political and social theory to understand citizenship, political economy, and sovereignty.

Citizenship

If civic agriculture is fundamental (however problematic) about public goods, community development, and citizenship in rural communities, then it stands to reason that understanding how and where small business owners and consumers contribute to democracy is a productive research direction for civic agriculture. The kinds of citizenship identified and advocated by theories of civic agriculture require analysis (as opposed to description) of the political imaginaries that constitute its “food citizens.” Citizenship is

coproduced through the repeated performances of individuals and communities across space and time, and citizenship itself is a mutable and potentially subversive category. While we understand that alternative forms of belonging and allegiance operate in civic agriculture, less well understood are the ways these citizenship forms work in liberal democracies; the implications of food citizenship for national citizenship (and vice versa); and how, when, and where these political imaginaries and subjects are created.

Political Economy

Market relations are implicit in many of the forms of civic agriculture identified by its theorists and practitioners. While there is widespread public agreement on the purported benefits of small businesses to communities, theories of civic agriculture fail to identify whether and how local food systems do or do not transform the inequities of capitalist social relations in rural communities. Additionally, many of the methods of practicing civic agriculture involve either modified capitalist relations (i.e., CSAs) or the decommodification of food (community gardens), and are not small businesses at all. What role do these transformations of social relations play in civic agriculture, and might they be more productive of public goods than small businesses? Trauger and Passidomo (2012) identify “postcapitalist politics” in local food systems as central to promoting civic agriculture enterprises and, as such, constitute a productive framework for future research.

Food Sovereignty

Civic agriculture takes issue with both the state in its policies and the market for its global reach. At the same time, civic agriculture appeals to the market to redress social inequities in rural communities. Political theorists suggest that the state and market are not easily extricated and that appeals to the state or the market for solutions must contend with both. Food sovereignty as a set of spatial and territorial strategies to contest

state and capital control of food and agriculture, and promote democracy and autonomy in the gaps that exist in state/capital sovereignty, rejects state or market solutions and appeals to direct action instead. Community-based agriculture on squatted land; community distribution centers; seed-saving collectives; non-commodified food exchanges; and/or food production, consumption, and distribution practices that fall outside juridical structures all contribute to civic agriculture’s aims, but also challenge its central assertions about small businesses. Food sovereignty may thus produce some helpful allies to civic agriculture, but may also shift its core definition to include direct action and non-commodified food exchanges. Research on the relationship between food sovereignty and civic agriculture thus constitutes an emerging area of inquiry.

Summary

Civic agriculture is a term used to capture entrepreneurial activity on farms that is designed to foster community development, economically embedded activity, and public goods. Local food systems are central to civic agriculture’s descriptions of a future of agriculture in what community and social needs are taken into account. Research on civic agriculture has shown how community-scale partnerships, such as farm-to-school initiatives, could contribute to economically viable farming enterprises as well as public goods such as better food environments in schools. However, critics are concerned about the centrality of market relations to civic agriculture and question the assumption that consumption equals citizenship or that small businesses generate equity. Future research directions may include revisiting the theory of civic agriculture to accommodate non-market relations as well as broader social justice issues in rural and urban communities.

Introduction

Clean milk is a name used to refer to milk created by technological means without the need for cows.

It must be distinguished from plant-based “milks” – drinks approximating milk made from the likes of soy, nuts, rice, coconut, and so forth – as it aims to replicate dairy at a molecular level. The most notable producer of clean milk is Perfect Day (formerly Muufri), a biotechnology start-up funded by New Harvest, a charitable organization that has also funded research into the development of clean (in vitro) meat. However, home biohackers – including those associated with the US-based Real Vegan Cheese project – are pursuing similar goals. Perfect Day’s milk is set to be commercially launched in 2018, somewhat sooner than even optimistic launch dates for clean meat products.

One might assume that the ethical issues raised by clean milk parallel those raised by clean meat. While this is true to an extent, clean milk requires independent attention, at least because (1) the technology used to create clean milk is very different from the technology used to create clean meat, and (2) different ethical issues attach to the consumption of meat than attach to the consumption of milk.

This entry will first set out the technology behind clean milk and the broad ethical concerns that have motivated or could motivate individuals to support its development/adoption. It will then explore three issues that could be used to support the contemporary dairy industry over a hypothetical clean milk industry. Next will come three issues that may motivate *existing* critics of dairy to also oppose clean milk. After this will come three challenges to clean milk drawing from wider concerns in the food movement.

Technology and Promise

Perfect Day’s milk is produced using a process far closer to the brewing of beer than the in vitro process utilized by those developing clean meat. Perfect Day’s innovation comes in the use of yeast that has been modified with cattle DNA. This DNA, importantly, has been physically printed based on information sourced from existing scientific enquiry – no living cow is involved. Once printed, the DNA is inserted into the yeast. The

yeast – dubbed “Buttercup” – is then mixed with water and plant-based sugars. Fermentation occurs, and, after filtration and the addition of various plant-based nutrients, Perfect Day is left with a highly pure milk, lacking in the hormones, antibodies, blood-serum proteins, and other elements found in many of the products of contemporary dairy farming. Perfect Day’s milk also lacks cholesterol (associated with health risks), lactose (which can be digested by only a relatively small portion of the world’s human population), and bacteria (thus limiting the need for pasteurization and refrigeration.) For more on the science behind the product, see (Perfect Day [n.d.](#); Pandya 2014; Datar et al. 2016.)

This base of clean milk can easily be modified. In principle, the process could also be used to create goats’ milk, sheep’s milk, camels’ milk, and so forth – even human breastmilk. Given the high costs and unsteady supply associated with human breastmilk, the development of bioengineered breastmilk could revolutionize infant healthcare. It would also aid those parents who seek to feed children breastmilk but who cannot provide it themselves.

Perfect Day’s engineers are not the only people producing clean milk, and Perfect Day’s method is not the only way that clean milk could be produced; indeed, New Harvest seeks to “fuel academic research for the many other cell culture techniques” beyond fermentation (Datar et al. 2016, 124–5). Meanwhile, independently of New Harvest, biohackers associated with the hackerspaces BioCurious and Counterculture Labs are utilizing CRISPR, a newly developed gene-editing technique, to create “Real Vegan Cheese.” They, too, use genetically modified yeast to produce milk proteins.

Both Perfect Day and the Real Vegan Cheese project arise ultimately from dissatisfaction with vegan alternatives to dairy products. This gives an idea of why clean milk might be supported. A first concern looks to animals, whether this is framed in terms of animal welfare, animal rights, or some other normative framework. There are over 250 million dairy cattle worldwide (CIWF 2012). Standard Western dairy-farming practices – which are the most productive – see cows forcibly

impregnated, with their offspring separated from them shortly after birth. Males and “surplus” females are killed or enter the meat industry. Once cows have reached the end of their optimally productive lifespan (perhaps at around a quarter of their “natural” lifespan), they too are killed. These and associated practices – dehorning, branding, transport, confinement, etc. – raise concerns for advocates of animal welfare and animal rights. Clean milk production, on the other hand, requires no animal input. (This contrasts with clean meat production, which – with current production methods – needs animals for the acquisition of source cells, and perhaps in other ways.)

The contemporary dairy industry also raises environmental concerns. A report from the Food and Agricultural Organization of the United Nations found that global milk production contributed 2.7% of anthropogenic greenhouse gas emissions in 2007, and this was upped to 4% with the inclusion of the raising of “surplus” calves for meat (Gerber et al. 2010). Also significant is the industry’s energy use, land use, water use, and pollution. By contrast, preliminary analysis by the conservation biologist Mark Steer found that, compared “to conventionally produced milk, [Perfect Day’s clean milk] involves approximately 24–84% lower energy use, 98% lower water use, 77–91% lower land use, and 35–65% lower [greenhouse gas] emissions” (2015, 1). These environmental impacts are contributing to damage to the global ecosystem as well as harm to humans and other animals. These environmental concerns, however, are not the only way that clean milk has potential to limit harm to humans: The lower land use speaks to clean milk’s potential as a factor in ongoing discussions about feeding a rapidly growing world population, and it is worth noting that a move away from the antibiotic use of contemporary dairy farming could play a part in stemming the rise of antibiotic-resistant superbugs.

The *prima facie* case for supporting clean milk is thus compelling; the technology offers the chance for consumers to have milk while limiting their contribution to harm to animals, the environment, and other humans. There are, nonetheless, a range of ethical challenges one could raise.

Clean Milk and the Dairy Industry

Clean Milk and the Ontology of Milk

Proponents of the contemporary dairy industry can be expected to challenge the idea that clean milk is milk. While it is – in principle – indistinguishable from cow’s milk in terms of chemical make-up, taste, and texture, one could plausibly hold that milk needs to have come from the mammary gland of an animal. This dispute is not merely academic. There is political and marketing power in the words “milk” and “dairy,” and this is recognized by the contemporary dairy industry. A parallel debate took place in the European Union in 2017, where a court found that plant-based products (with a few exceptions) could not be sold as “milk,” “butter,” or “cheese.” Similar regulatory barriers exist elsewhere.

A related issue concerns whether clean milk can truly replace the culinary value of dairy. People who continue to use dairy products despite an awareness of the harms of the dairy industry might appeal to the fact that plant-based alternatives to dairy (e.g., soy-based “milk” and “cheese”) have different tastes and textures to dairy products. These culinary values can be replaced by clean milk, so defenders of the contemporary dairy industry will have to appeal to other values. Perhaps such an argument would draw upon a claim about the value of a relationship to animals or the land that milk consumption offers, but the advocate would need to explain how these relationships work, and, if they offer *culinary* value, in what sense they change the nature of milk *qua* food.

Clean Milk and the Loss of an Industry

The existing dairy industry relies on both consumer acceptance and governmental support (including subsidies). Like any situation in which consumers shift support from one product to another, widespread uptake of clean milk may mean a change in the kind of work available and a change in the amount of space devoted to the dairy industry and its products – physically, culturally, politically, and so forth. Those who benefit from the existing dairy industry or who conceive of it as a part of their identity are thus likely to be worried

about widespread acceptance of clean milk. Perhaps they have reason to be worried, given that New Harvest explicitly seeks a “post-animal bioeconomy” (Datar et al. 2016, 127).

A change to – or elimination of – traditional industries and ways of life is the standard result of social and technological progress. While critics of food biotechnology might want to frame their concerns as part of a broader conservatism, this could involve biting unappetizing bullets concerning *other* social and technological advancements. If these critics do not wish to frame their challenge as a part of a broader conservatism, some account is owed that identifies the contemporary dairy industry as something particularly valuable and worthy of retention. As with the kinds of culinary value discussed above, such an argument could draw upon some claim about relationships with animals or the land. This argument is, however, a hard sell. It is not clear that contemporary farming practices *do* involve positive and valuable relationships with animals and the land, and even if they do, it is not clear that the positives of these relationships could outweigh the harms of the contemporary dairy industry or could not be sought elsewhere.

Perhaps locavores and other “compassionate carnivores” will want to challenge clean milk *and* industrial animal agriculture and call instead for small-scale, local farming, claiming that *this* farming allows people to have an appropriate relationship with food, animals, and the land (cf. Stănescu 2016). But it now sounds like clean milk is hardly the problem; indeed, Perfect Day expresses support for farmers engaged in environmentally responsible, small-scale humane farming (Perfect Day n.d.), and even some animal rights advocates can allow for a form of small-scale dairy farming – though they will be opposed to the infliction of death and suffering upon dairy cows or their calves.

Clean Milk and the Loss of Animals

If dairy production were to shift from contemporary farming practices to clean milk, there would be fewer cows in the world. From an animal rights or climate ethics perspective, this is almost

certainly a positive. Other kinds of accounts, however, can frame this in a different way. If we assume that dairy cows live minimally happy lives, and we assume an account of population ethics according to which we can be obliged to maximize the creation of happy lives, it could be that we are wrong to support clean milk because in so doing we fail to create many happy lives.

This kind of worry has a place in the animal ethics literature. It is associated strongly with so-called total utilitarianism, though the position is not one that has many vocal advocates (or, minimally, the conclusion that we should be creating many happy lives is one that has few vocal advocates). This argument against clean milk can be challenged on several grounds. First, and most importantly, these accounts of population ethics invite many problems – including the infamous “repugnant conclusion.” Second, it could be that dairy cows do not live minimally happy lives. Third, there are any number of other consequences that need to be considered, along with other possible policy proposals. For instance, continued societal support for dairy industry may result in widespread harm in the medium term (through climate change, public-health effects, and so forth), and land currently used for dairy production could house many wild animals. Indeed, if we are serious about maximizing happy animals, perhaps we should convert existing dairy farms into spaces for housing many happy (say) hamsters.

Clean Milk and Opponents of Dairy

Milk and Respect for Animals

Many vegans and animal advocates will be uneasy about the development of clean milk as it perpetuates the idea that milk is food for humans. Rather than finding replacements for milk, these advocates might argue, we should be challenging the centrality of milk in western food systems. It could even be claimed that the consumption of milk(-like products) is inherently wrong, regardless of sourcing. These kinds of arguments have been suggested when it comes to clean meat (Miller 2012), and while one could affirm such

arguments in the case of clean meat while rejecting them in the case of clean milk (Sinclair 2016, 230–3), it could be that *all* animal foods and their imitations should be challenged.

The obvious response is to claim that there is nothing inherently wrong with consuming animal products and that such consumption only becomes wrong when it contributes to harm to animals. The critic of milk consumption per se could in turn claim that the consumption of milk does involve harms to animals; disrespect, perhaps, or a contribution to indirect harms.

A slightly different approach to the wrongness of milk consumption would draw upon the vegan slogan that as the cow is “not your mother, [what she produces is] not your milk,” or the idea that milk is food for calves, not for us. Starting with these ideas, one can affirm mothers breastfeeding children while condemning other forms of milk consumption. Generalizing these slogans into ethical principles may result in some surprising conclusions when it comes to examples of intuitively innocuous and autonomous milk sharing in human culture and history – including interspecies milk sharing. But these bullets may not be so hard to bite.

It is worth noting that the defender of clean milk could appeal to the product as a “least worst” or “non-ideal” alternative to the current milk industry. Perhaps, it could be said, no one would consume milk in an ideal world, but – as we do not live in an ideal world – we should be ready to offer lukewarm support for clean milk, not least as it offers an alternative to the contemporary dairy industry in which (certain egregious) harms to animals are removed.

Milk and Race

The centrality of milk in Western food culture – and especially the centrality of milk in Western dietary advice – has been framed as problematically ethnocentric, as large proportions of the world’s population have “allergies” to dairy (see Gaard 2013). Claims about milk and lactose intolerance have motivated even found a place in racist rhetoric. This opens the door to concerns about milk completely independent of the kinds of concerns (animal welfare/rights, the environment,

etc.) that have motivated and will motivate the development and uptake of clean milk. The technology, nonetheless, may be a valuable one for developing forms of milk that *are* accessible to those peoples who tend to be unable to digest milk; versions of milk could be, and are being, developed that do not contain the problematic components.

Milk and Health

Certain advocates of plant-based food eschew milk because they perceive it as particularly unhealthy. Depending on their reasons for believing that milk is unhealthy, they may perceive clean milk as unhealthy. Those who hold that milk is inherently (or overwhelmingly) unhealthy might even advocate for sales restrictions on milk – clean or otherwise. For example, they could argue in favor of the inclusion of warning labels, the banning of the sale of such products to children, or the removal of these products from schools. Such arguments would rely not only on contentious ethico-political claims about the reach of state paternalism but also contentious empirical matters about the healthfulness of milk.

There are reasons to believe that critics of the healthfulness of milk produced by the current milk industry might be open to clean milk. Clean milk products will lack certain impurities and additives that can be found in the products of the current milk industry (hormones, antibiotics, etc.) and can also be modified to add or remove other components – for example, Perfect Day’s milk lacks cholesterol. Whether this possibility will open these health-conscious consumers to clean milk will depend on what it is about milk that worries them in the first place.

It is also possible that people will perceive health risks with clean milk that they do not perceive with milk produced by the current milk industry (cf. Laestadius 2015). This is a common response to new technological developments – while producers of clean milk certainly have an ethical responsibility to ensure that the product is a safe one, it is likely that this presents more of a marketing challenge than a genuine scientific or ethical issue.

Other Concerns

Clean Milk and GMOs

The production of clean milk (unlike, incidentally, the production of clean meat) involves genetic modification. Though it is only the yeast that is genetically modified – the final product is GMO-free – consumers with a principled objection to GMOs are likely going to be unimpressed by clean milk. Consumers with a more nuanced approach to GMOs are unlikely to be worried by clean milk, as its production requires genetic modification only in the most controlled and contained environments.

Clean Milk and Capitalism

One challenge that has been made to the production of clean meat is that it potentially shifts control of food production into the hands of corporations (Miller 2012). This kind of thought might be deployed in criticism of clean milk – especially while there is only a single company utilizing the technology commercially. One counter-thought points to the idea of democratizing clean meat production (Weele and Driessen 2013), and this, too, is possible when it comes to clean milk. Indeed, Perfect Day, New Harvest, and the hackerspaces supporting the development of Real Vegan Cheese all have strong commitments to open-source information. Given the motivation of many of the people involved in these projects, it would be counter-productive for them to limit the spread or uptake of the technology. For Bruce Friedrich, of The Good Food Institute – a second leading not-for-profit concerned with clean animal products – “the more researchers in the space the better, as they will leverage one another’s knowledge and bring increasingly better products to market faster, at a better price” (Bhumitra and Friedrich 2016, 199).

It is undeniable that Perfect Day – like many biotechnology start-ups – exists in a context of venture capitalism. Critics of contemporary capitalism, of course, are likely critical of this model. It is also undeniable that the development of clean milk has taken place in the context of a consumer-choice model of food distribution, and it is likely to thrive or fail in that context. Again, committed

critics of capitalism may challenge this model, though it is hard to see why they would have any *particular* quarrel with clean-milk producers.

Clean Milk and Naturalness

Perhaps the greatest challenge clean milk is likely to face when it comes to consumer acceptance is the idea that producing milk using genetically modified yeast is problematically “unnatural.” This is certainly a concern that has been seen in the public response to clean meat (see, e.g., Laestadius 2015), and – though there is no published research on public perceptions of clean milk – it is likely that similar concerns will be raised.

These kinds of naturalness worries are common in discussions about the ethics and philosophy of food and are notoriously problematic. An account is owed of what makes something “natural” and in what sense something being “natural” is a good thing. Even if these problems can be overcome, naturalness arguments are not an easy friend to animal agriculture. Presumably, one must weigh the “unnaturalness” of clean milk against the “unnaturalness” of contemporary agricultural practices. One must also weigh the “unnaturalness” of clean milk against the benefits of clean milk, and this includes the benefits that clean milk could provide to the “natural,” including the preservation of “natural” environments (in contrast to how these environments would fare were the contemporary dairy industry to continue unabated). Again, it may be that naturalness objections present more of a marketing challenge than a genuine ethical hurdle to overcome.

Conclusion

Clean milk presents an alternative to milk produced by animal agriculture, allowing people to have the nutritional and culinary benefits of milk without the harmful effects of the dairy industry – to animals, the environment, and humans. Though it will soon be commercially available, it has received little academic attention.

It can expect to be challenged by apologists for the contemporary dairy industry, who may

challenge its status as “milk,” lament the harm it could do to the dairy industry and ways of life associated with it, and perhaps question the ethics of creating fewer cows. It can also expect to be challenged by certain *critics* of the contemporary dairy industry. For some vegans, it will not go far enough – for them, the consumption of dairy will always be wrong. Others may worry about the healthfulness of milk as such and may raise worries about the interplay of milk and race/racism. Other kinds of challenges might include worries about the use of genetically modified organisms in the food industry, the control of food distribution by capitalist interests, and the “naturalness” of certain food production methods.

Defenders of clean milk have an array of arguments at their disposal to respond to these challenges. Ultimately, however, the success of clean milk is unlikely to come down to close argumentation in academic journals and instead to the messy and irrational world of consumer acceptance. It is not ethicists who will determine the success of clean milk, but marketers.

Global warming; Greenhouse emissions

Introduction: Wicked Problems

There has been much public debate about the reality and about the human responsibility for the greenhouse gases that cause global warming and about obligations to those worst affected, as well as to future generations. Scientists overwhelmingly concur in accepting the evidence for these, although they may differ about the speed and extent of developments.

Donald Brown (Associate Professor of Environmental Ethics, Science, and Law at Penn State University) argued in July 2010 that:

- (a) Climate change must be understood as an ethical problem, a fact that requires that scientific uncertainties about climate change be approached in a precautionary manner by those who are tempted to use scientific uncertainty as an excuse for putting others at risk.
- (b) The consensus position on climate change science is entitled to respect, despite some scientific uncertainty about the timing and magnitude of climate change impacts.

As evidenced elsewhere in this volume, there is a long history of analysis and of discussion about the ethics of food, its production and distribution, and their impact on society and nature. Recently there has developed a growing body of discussion and analysis of the ethics of climate change (Bell 2010). There has, however, been relatively little focus, so far, on the ethical implications of the specific impact of climate change on food or of food production on climate change.

Climate change has been described as a “wicked problem,” complex, uncertain, and contradictory in its impacts and in its practical and ethical imperatives. All people are both responsible and vulnerable, although to varying degrees, and the cooperative action of all (despite conflicting interests and rights) both locally and globally will be needed to confront the threats, including those to food production and prices, and the danger of spreading hunger.

Climate Change

Warming

The IPCC (International Panel on Climate Change) fourth report stated in 2007 that the anthropogenic (caused by humans) warming of the climate system was “unequivocal.” The first decade of the new century now ranks as the hottest decade globally on record, with a further rise of up to 0.19° since 1995, according to the British Meteorological Office, using monthly measurements from over 3000 weather stations around the world. Pittcock (2009) demonstrates that this warming (unlike that in earlier historical periods) is not due to natural changes, such as in solar activity, sunspots, etc. Plants, animals, birds, and butterflies have been responding to changes in climate zones and seasonal dates, progressively moving their habitats and breeding grounds towards the poles, since the mid-twentieth century.

There is clear evidence that climate change has already been speeding up. The Australian CSIRO (Commonwealth Scientific and Industrial Research Organisation) *State of the Climate* report in March 2012 noted that each decade since the 1950s had been warmer than the previous one, with most of the heat concentrated in the oceans. Thermal expansion had caused global sea levels to rise 210 mm above the level of the 1880s, growing almost twice as fast between 1993 and 2011 than during the entire twentieth century. Evidence from satellites indicated that Arctic ice was melting faster in 2011 than the record-breaking speed of 2010, adding to the rising sea levels. The researchers had no doubt that this was caused by anthropogenic global warming and not by any natural weather

variability. Such rates indicate the Arctic could be ice-free in summer well before mid-century, 40 years earlier than had been anticipated by the IPCC in their 2007 report. In August 2011 a crew was able to row a boat, for the first time, through clear water to the magnetic North Pole.

When unusually cold and wet weather in the northern winters of 2011 and 2012 spread public doubts about global warming, scientists were able to demonstrate how changing deep ocean currents and polar winds, linked to the rapid melting of Arctic sea ice, had produced a localized regional cooling despite continuing overall warming.

Rising Greenhouse Gases

Much is known with confidence by climate scientists about the mechanism, first proposed in 1822 by Fourier and quantified in 1898 by Arrhenius, which links increasing anthropogenic greenhouse gases in the atmosphere to global warming. In January 2006 a British Antarctic survey, analyzing CO₂ (carbon dioxide) in air bubbles in crevasse ice in the peninsula, reported it had found that recent levels were higher than any in the previous 800,000 years. The speed of the recent rise, from 280 parts per million (ppm) before the industrial revolution to a provisional estimate of 393 in 2012, is unprecedented. Measurements carried out annually since 1958, in the unpolluted atmosphere at Mauna Loa, show the rise has accelerated, from 1% a year in the 1980s to around 3% by the end of the “noughties,” as energy use in developed and developing countries continues to rise. The *State of the Climate* report estimated that global carbon dioxide emissions grew by 5.9% during the 12 months of 2009–2010, drastically reversing the small decline of the previous year.

Growing Scientific Consensus

As a result of the accumulating data and confidence of climate science since the 1980s, there has been a growing world scientific consensus about the reality of global warming, its likely human causes and long-term risks, and, more recently and hesitantly, about its current impacts. While in 1995 most scientists surveyed (other than specialist climate scientists) believed the effects of global warming were still far away, a decade later

only a few doubted they were already becoming manifest.

In July 2005 the heads of 11 influential national science academies (Brazil, Canada, China, France, Germany, India, Italy, Japan, Russia, the UK, and the USA) wrote to the G8 leaders warning that global climate change was “a clear and increasing threat” and that they must act immediately. They outlined strong and long-term evidence from direct measurements of increasing ocean and air temperatures and from rising average global sea levels, retreating glaciers and changes to many physical and biological systems.

Despite the failure of the global conference in Copenhagen in 2009 to agree action on climate change, a new push by sceptics and a public opinion distracted by problems in the global economy, no decline in concern has occurred among scientists themselves. Delegates from 62 academies to the April 2010 meeting of the Inter-Academy Panel – the global network of the world’s science academies – were asked what global issues concerned them most, “looking ahead to 2020.” By a substantial margin, climate change ranked first among scientists from both rich and poor countries. In May 2010 a letter signed by 284 members of the US National Academy of Sciences was published in *Science* (DOI: <https://doi.org/10.1126/science.328.5979.689>) claiming that:

There is compelling, comprehensive and consistent objective evidence that humans are changing the climate in ways that threaten our societies and the ecosystems on which we depend. (pp. 689–690)

A study by Stanford University, published in *Proceedings of the National Academy of Sciences* in June 2010, surveyed the top 100 climate researchers in the world and found that 97% of them agreed with the IPCC’s 2007 assessment of the reality and human causation of climate change.

Climate Change and Ethics

Attribution of Blame

This is not straightforward. All emissions travel right round the world so there is no direct relationship between the location of cause and of effect. Developed countries are responsible for

by far the most greenhouse gases accumulated in the atmosphere, but China has now become the largest emitter in total and with fastest increase (though still with much lower levels per capita). Other large developing countries such as India and Brazil are catching up through rising energy use and meat consumption and deforestation. Deforestation is propelling Indonesia to the top emitting ranks, and rice production in flooded Asian paddy fields creates methane. On the other hand, the footprint of Britain's imported food is surely their responsibility, and while Australia's small population is not directly responsible for much greenhouse gas, the country benefits from being one of the largest exporters of coal (and also of beef) in the world.

Nature knows neither malice nor justice. Impoverished Bangladesh and Nepal are particularly vulnerable to rising seas or melting ice, although they have contributed little to the cause, but London and New York could in the future also be flooded, and if the Gulf Stream ever fails, it is rich north European countries that will suffer, reverting to cold temperatures like those of the same latitude in northern Canada.

Short-Term and Long-Term Ethical Priorities

There is a human obligation to offer immediate help to victims of disaster and poverty and also a responsibility in justice to offer timely assistance and refuge, and perhaps also compensation, to those struck by the results of our collective actions. On the other hand, long-term issues of intergenerational justice also call for major costly mitigation measures to slow and halt, or even reverse our greenhouse emissions, even if their impact will occur to people unknown, in a distant future. In these choices, effectiveness may conflict with the equity claims of today. The rights as well as the short-term interests of ourselves and our children may conflict with the needs of many future generations or the survival of other species.

The need for immediate mitigation cannot be ignored. There is considerable uncertainty in the projections and scenarios, but many climate scientists believe the IPCC is underestimating the window of time still available for remedial action. Some climate scientists have estimated that effects

might move up smoothly as temperatures rise by 3–4°. Beyond that it could shift rapidly to 7° and more, with irreversible catastrophic consequences.

The unpredictable dangers of sudden irreversible tipping points mean that mitigation may soon be too late. As oceans absorb CO₂, they become more acidic, and this reduces their future ability to absorb more. As ice melts the exposed dark surface ceases to reflect back the sun's rays into space and the newly exposed frozen methane evaporates from the tundra. As temperature rises, forests burn and release their carbon. Such effects are particularly hard to quantify or predict and have not been factored into IPCC assessments of what constitutes a dangerous level of greenhouse gas or of temperature.

Food, Climate Change, and Ethics

Threats to Food Production from Climate Change

Demographers are projecting a human population of nine billion by 2050, while dramatic changes in ocean and atmospheric currents, precipitation, and temperatures would significantly worsen the opportunities for feeding them all, even on the most optimistic scenarios.

Shifting climate zones, ecosystems, and weather patterns are already manifest and will increase. There is a potential loss of melt water from the Andes and the Himalayas to rivers essential for food production for many millions in South America and in China, while droughts in East Africa may threaten the sources of the Nile. There is evidence that some of the world's major underground aquifers are becoming exhausted (*New Scientist*). Salination from rising seas is already evident in Bangladesh and Pacific Islands. Floods elsewhere, such as the record-breaking rains covering much of southeast Australia in March 2012, cannot be simply redistributed to areas lacking rain.

Ocean acidification is threatening fish stocks. Canadian scientists reported in *Nature*, in July 2011, a strong link between higher sea surface temperatures and a major decline, since 1950, of around 40%, in phytoplankton which forms the basis of the marine food chain.

IFPRI (International Food Policy Research Institute) argues that the successes of the green revolution of the 1960s led to complacency and declining investment in agricultural productivity. Although numbers of hungry and malnourished in the world declined until the 1990s, they have again started to rise, and to feed the projected world population, a new wave of innovation and investment is needed.

IFPRI models show the negative effects of climate change by 2050, under IPCC, NCAR (National Centre for Atmospheric Research), and CSIRO scenarios for temperature, evaporation, and precipitation, unless dramatic action is taken. With expected global average temperature rises by then of about 1C, yields in developing countries would decline for the most important crops especially for irrigated crops in South Asia. Price increases would affect rice, wheat, maize, and soybeans with higher feed prices for meat. Calorie availability in 2050 would decline relative to 2000 level throughout the developing world, increasing child malnutrition by 20% relative to a world with no climate change (2009, 2010).

David Lobell reported in *Nature*, in March 2011, on trials showing African maize yields were particularly sensitive to the number of very hot days, which had been increasing faster than average temperatures. He predicted a rise of 1C would reduce yields across two thirds of the maize-growing region of Africa, with losses of 20% or more by mid-century.

IFPRI thinks such changes might conceivably be offset and made “manageable” by well-designed investments in land and water productivity. However, after mid-century, the climate change challenges to food and water would become much more severe, with global average temperature rises between 2 and 4°. “Starting the process of slowing emissions growth today is critical to avoiding a calamitous post-2050 future” (IFPRI 2010, pp. xx, xxi).

Climate extremes producing disasters such as floods, storms, droughts, and heat waves that can impact heavily on global food production and prices have become more common over the last half century. Some scientists are beginning to demonstrate that anthropogenic greenhouse

emissions have contributed significantly to the frequency and intensity of specific disasters such as the Russian heat wave and drought of 2010. This led to an embargo on food exports which played some part in the global rise in food prices, which in turn was one of the causes of the “Arab Spring” revolts. Similar attribution is being claimed for the return of drought to east Africa in 2012.

Increasingly sophisticated model projections indicate these dangers will inevitably grow significantly by mid-century, as many greenhouse gas concentrations are already “locked in” to the atmosphere and deep oceans, and will dissipate only over centuries and millennia. These will cumulate further as humans continue to emit. The mechanisms are well understood. Nonetheless, the high degree of natural variability, the difficulty of disentangling multiple complex natural and human causes, and the limited long-term data for rare extremes have made most scientists hesitate to predict or attribute causation for specific, already manifest, disasters. However, detailed case studies are beginning to trace such a direct causal chain from human actions to harm already done.

Threats to Climate from Food Production

In 2009 the Carbon Footprint of Nations index, by the Norwegian Institute of Science and Technology, calculated that all food production contributed 20% of global greenhouse gas emissions from goods consumed. This included, among other sources, the carbon dioxide emitted by fuel, the nitrous oxide that is emitted by manure, and fertilizers and the methane produced by decaying vegetation in flooded rice paddies and most important by the belching of ruminant animals such as cattle and sheep (both grain and grass fed). Methane and nitrous oxide are far more powerful greenhouse gasses (measured in CO₂ equivalents) than carbon dioxide, although they decay more rapidly. Rising world consumption of beef is one of the most important accelerators of climate change.

Ethical Responses

There are many alternative approaches to mitigating the dangers of climate change and preparing to adapt to its consequences. All have winners and

losers and associated costs and must accept a substantial level of uncertainty. There is no simple factual calculation nor ethical Ariadne thread to guide us through this labyrinth. A simple economic cost-benefit analysis will not be appropriate because such analysis always discounts the future and cannot take into account our long-term obligations to our descendants and to the diversity of life on earth. Ethical first principles will often also need to be compromised. The global nature of the causes, vulnerabilities, and actors mandates choices that evoke trust in their fairness and further cooperative rather than confrontational approaches.

Choices and Policies

The Case of Biofuels

The production of biofuels, using as feedstock mainly maize in the USA, sugar cane in Brazil, and palm oil in Asia, was initially fostered by government subsidies and quotas in order to advance national energy self-sufficiency and farming interests. Their production has been growing rapidly over the first decade of the century. Maize ethanol produced in the USA went up from 175 m gallons in 1980 to 9 bn in 2008, about half of the global total. Biofuels have been increasingly presented as also a readily available and economically viable alternative to fossil fuels and, as such, now claim the moral high ground, despite their encroachment on agricultural and rain forest land.

Biofuels have been blamed for between 5% and 30% of the spike in global food prices in 2008, as well as their recurrence in 2010. Researchers have pointed to other factors including poor harvests, perhaps due themselves to climate change, low stocks, and especially to the explosion of global speculation leading to bubbles in food and oil commodity futures. There is little doubt, however, that the growth in biofuel cultivation made some contribution and that if this were expanded to meet future decarbonization targets, its effect on food supplies and prices could be substantial, hurting worst the poor around the world.

Does this then have to be a choice between immediate concerns about exacerbating world

hunger and long-term ethical imperatives to protect future generations from climate change? If so, then surely immediate life sustaining food production might have a strong claim to priority. The global rise in food prices was one element in provoking riots and revolts in many countries. An expanded pragmatism would indicate the need to avoid mitigation policies that could undermine any global unity of purpose in the face of climate change. On the other hand, if biofuels on arable land were indeed indispensable to mitigation, then the ethical dilemma might become unresolvable.

There are, furthermore, many important empirical questions. On the one hand, some maintain that current global food shortages are only due to maldistribution, waste, and inefficiency or to the diversion of crops to animal feed for growing meat consumption in wealthy and developing countries. Enough food they say could be produced on less land with improved cultivation or genetic engineering.

On the other hand, it is suggested that biofuel cultivation is itself responsible for significant greenhouse emissions, through forest clearances and the annual burning of cane fields. Recent satellite images showed that the latter is much more extensive than previously accounted for. It has been estimated that most biofuels used on UK roads do not meet environmental standards for water use, soil protection, or carbon emissions. A European commission study has found that when everything is calculated, many biofuels are as bad as crude oil; indeed palm, soya and rapeseed oil were worse. The most substantial advantage was for second-generation (2G) non-land-using ethanol and biodiesel. Such “win-win” fuels that do not compete with food production are in the pipeline, using feedstock based on saltwater algae or on desert jatropha and agave plants or on crop waste and biomass.

Arizona State University researchers say commercial algae farms are much more productive than cultivation for ethanol on arable land. All US biofuels could be replaced by algae oil on 800,000 ha of desert, allowing 16 million hectares of cropland to be planted with food, although considerable investment in pipelines would be needed. Major airlines and shipping companies are investigating a switch (Guardian Weekly).

It is claimed measures to shift government support to these alternatives could help mitigation without damaging food supplies and prices.

Changing Agricultural Practices

Agroforestry, as one example, is a natural resource management system that combines woody perennials with herbaceous crops and/or animals, either in some form of spatial arrangement or temporal sequence on the same land. It thus combines elements of both agriculture and forestry, producing increased overall yield, better water quality, optimization of capture and use of scarce rainwater, and improved habitat for both humans and wildlife, and it can improve soil biota and fertility. In more recent times, agroforestry has been being considered as one of the strategies towards climate change adaptation. In 2006 the International Food Policy Research Institute calculated that it could sequester five times more carbon from the atmosphere than ordinary croplands. They estimated that by the year 2040, agroforestry farms could sequester nearly 600 million metric tons of carbon globally compared with about 120 million metric tons for cropland (Tolentino et al. 2010).

Another proposal seeks to learn from what is being discovered about the making and use of biochar, or *terra preta*, over wide areas of the Amazon basin, for thousands of years, by pre-Colombian farmers. The carbon extracted from the atmosphere by plants normally returns there again. However, with biochar, a sealed non-polluting pyrolysis converts plant and other organic waste, including straw, into a non-biodegradable charcoal that can remain permanently in the soil, adding significantly to its fertility. The Australian CSIRO thinks the idea is promising but in need of more research on its suitability for different kinds of soil, on how much carbon might be removed, and on how much waste it could reprocess. A number of pilot projects are in the pipeline (Flannery 2010).

Changing Consumer Choices

Individual consumers are unlikely to have the relevant knowledge or power to affect fuel and food production methods. There are, however,

also some relatively easy individual decisions about the food humans eat that may have immediate and far-reaching impacts.

The United Nations FAO (Food and Agriculture Organization) reported in 2006 that livestock generated 18% of global greenhouse gas equivalents (including CO₂, methane, and nitrous oxide), which was more than the transport sector. As global population increased and major developing countries became richer, global meat and milk production was projected to double by 2050. A US study found reducing “food miles,” by choosing only local products, would have far less impact on emissions than even a relatively small dietary shift away from red meat and dairy foods. The Garnaut report estimated that while beef contributes more than half of all global warming from agriculture, poultry contributed only 1%.

It is unlikely that many could be persuaded to adopt a vegan diet, but slight changes in ordinary food selections could have significant impact. If many people decided to choose egg and bacon for breakfast, more often than beef sausages, fish and chips or chicken nuggets for lunch more often than beef hamburgers, and substituted roast chicken or turkey for roast lamb or beef on Sundays, the impact on greenhouse gases could be substantial. Ruminant meats could be kept as a treat for special occasions. Such choices would have the dual benefit of reducing greenhouse gases and increasing global food production.

Other Ethical Debates

There are many other long-established ethical questions linked to the production, distribution, and consumption of food, where climate change exacerbates or complicates the issue. Some of these are discussed at greater length in other sections of this encyclopedia. Sometimes one or indeed both sides in longstanding debates can find new arguments in the need for climate change mitigation or help in adapting to its impacts.

Large hydroelectric projects, long contested for their effect on wilderness and on local people, find additional positive arguments in providing clean energy for developing countries in Asia, South America, and Africa. They can also, however, sometimes severely affect water flows

downstream, exacerbating impacts from climate change on agriculture and fishing. It is claimed lakes on the lower reaches of the Yangtze are already drying out, threatening a dust bowl, because the Three Gorges dam blocks the water flow. Droughts and the drying up of glaciers may also interfere with the generation of hydroelectricity.

There are longstanding debates between supporters of local community autonomy and of unimpeded national or global markets. Advocates of *locavore* practices (eating local produce) in Europe have long been in conflict with opponents of subsidies and tariffs that can exclude farmers in poor African countries from global markets. The new argument about the damage caused by the transport emissions of “food miles” is countered by those who point to how trade in food reduces waste and how agriculture in sunnier climates has a smaller carbon footprint.

Research and investment are already ongoing into much-needed drought-resistant, more productive seeds that need less water and nitrogen fertilizer, but they confront opposition to genetic modification and to exclusive corporate patents. China is engaged in selective breeding of “green super rice” which is claimed to produce more grain as well as being more resistant to droughts, floods, salty water, insects, and disease. It is not clear to whom or at what price these might be made available.

Oliver de Schutter, the UN special rapporteur on the right to food, has highlighted the crucial importance of empowering small farmers. He questioned whether the classic green revolution prescriptions of the 1970s, involving improved seeds, chemical fertilizers, and pesticides, were viable in a world running out of fossil fuel energies and in which control over these inputs was in the hands of a few very large corporations. Both sides of this debate are extensively canvassed in special editions of *Cosmos* and *IJSIF*.

Summary

Given the scale and urgency of the need both for food and for climate mitigation, strong ethical cases might be made for priority to be given to

measures that take account of current needs and rights, on the one hand, but also, on the other, for those most effective for the long term. An accommodation through expanded pragmatism must be sought, with substantial investment and research into measures that can begin to reconcile both needs.

The precautionary principal enjoins us to tread warily and to avoid action if significant harm from it is possible, even if not certain. It has been argued as appropriate for novel human interventions in nature, such as gene technology. Unfortunately it is now too late to be of much help in mitigating climate risks. The human interventions that initiated the buildup of greenhouse gases commenced long ago, and their long-lived effects in the atmosphere and the deep oceans will not dissipate for centuries and may mean human society is already close to or past a point of no return – a precautionary inaction is not a viable option.

More research and development to avoid or counteract the risks and to try and reconcile the opposing ethical imperatives is clearly needed urgently. Climate change is indeed a “wicked problem.” “Climate change is an issue of survival, and equity is the price of survival” (Aubrey Myer, interviewed in *Nature Climate change* January 2012, p. 17).

Community shared agriculture; Subscription farming

Introduction

Community-supported agriculture (CSA) is one of an array of alternative agricultural processes. Related terms include sustainable agriculture, local food systems, regenerative agriculture, alternative food networks, and civic agriculture. CSA is continually evolving as it adjusts and matures within the interstices of the global food system. Though there is increasing variation in CSA, it is essentially characterized as "... a localized food production and consumption system, organized to share farming risks between producers and consumers, practice ecologically sensitive forms of food production, and contribute to building community and educating the shareholders about agricultural processes and realities through their participation" (Feagan and Henderson 2009,

p. 203). Beyond these basics, CSA operations can vary considerably with respect to such things as how and where the "share" is accessed, opportunities for "working" shares, kinds of share products available, and presence of a "core" group. Importantly, CSA is a process that gives producers and consumers an opportunity to act intentionally on values and principles that are generally not feasible within the dominant food system.

In its "idealized" form, CSA is comprised of the following common characteristics: an intentional sharing of risks by the consumer/shareholder with the farmer/producer via payment of shares prior to the farming season, which ideally covers all real costs of production; a collaborative effort; a direct marketing form connecting consumers and producers; a means to help "localize" the food system; an ecologically responsible set of farming practices; and acts to educate consumers about this kind of farming relative to conventional food system characteristics.

Origins

CSA has its origins in two distinct though related sets of agricultural partnerships, practices, and values. The first, known as the Teikei movement (meaning partnership or cooperation), originated in Japan in the early 1970s by women concerned with ensuring healthy sources of food for their families and who initiated unique direct exchange partnership relationships with local farmers for organic food in order to do so (see Okumura 2004). The second sphere of influences are European in origin – most specifically those of German philosopher Rudolf Steiner's early 1900s anthroposophy and biodynamic farming concepts and from the German cooperative movement during this era. From this juncture, the bulk of CSA efforts both in North America and internationally are the outcome of the pioneering work of alternative food system advocate Robyn Van En in the United States. Indian Line Farm, established in 1986 in Massachusetts, is considered to be one of the first instances of CSA in the United States and was the result of efforts by Van En and others to put into practice these emerging values and

beliefs. Given this lineage, the Henderson and Van En (1999) “guide” to CSA can be considered a useful and informative accompaniment to more recent CSA practice and development (though also see Groh and McFadden 2000, for their well-known writing on CSA).

CSA practice spread in distinct pockets from there, with current registered CSA numbers in the range of 1650 in the United States (see Robyn Van En Center 2014), with some organizations claiming numbers in that country on the order of 4000 (Local Harvest 2014), and official US government sources suggesting numbers on the order of 12,500 (USDA 2012). CSA is also increasing, though in smaller numbers, in the United Kingdom (on the order of 50), Canada, France, Japan, Brazil, Holland, Denmark, Germany, Argentina, and Australia, with more recent examples in countries like Romania and China. In this light, the interest on the part of those involved in the Teikei movement in Japan regarding recent CSA experience in the United States is indicative of the dynamic character of alternative food system efforts within the broader conventional food systems environment (Okomura 2004).

The last 20 years has seen the unfolding of what McFadden (2004) describes as “waves” of CSA development, and these waves are mirrored by a diversity of CSA research as this agricultural form has evolved and as its interest level and membership has grown. Though not exhaustive, such research and writing on CSA includes themes like health and nutrition affects, community and place concepts, guides to development and implementation, personal experiences, motivational surveys and analysis, gender, changing form and structure, adaptation to context, contribution to dietary shifts, effects resulting from membership and participation, nonmember perspectives, demographics and concerns, political-economic analyses, equity and social justice issues, and historical antecedents and ideological roots (agrarian pastoralism, Japanese Teikei, Steiner philosophical traditions, etc.). Though these are all considered appropriate research themes, this entry does not explore any of them in depth. Rather, it provides basic context for

CSA, including commentary on demographic characteristics, form variations, concerns and critique, selected case studies, and on anticipated trends, referring to examples where appropriate.

CSA as Alternative Agriculture

CSA is considered variously as alternative, parallel, radical, and/or in opposition to the conventional (or industrial, modern, global) food system and is most commonly located in the so-called developed “north.” Generally, CSA is held as a response to concerns within the conventional agricultural and food systems with respect to:

- Increasing farm size and corresponding decrease in farm numbers
- Aging on-farm populations and loss of youth cohort to other forms of employment and to urban areas
- Loss/fragmentation of rural communities and local agricultural economies
- Degradation of agroecosystems, monocultural production impacts, and related on-farm issues around species and biodiversity loss, soil compaction and degradation, erosion concerns, habitat loss, etc.
- Health concerns perceived to be associated with various inputs employed – fossil fuel-based insecticides, herbicides, fungicides, fertilizers, genetically modified organisms (GMO), etc. and their perceived effects regarding diminished nutritive quality of, and contamination of, food and hence health
- Consolidation of food production and ownership under the auspices of both fewer and larger agribusiness entities, with related concerns around increasing distance between producers and consumers, “commodification” of food and associated economic vulnerabilities related to international market transactions, etc.
- Other off-farm issues like food miles and associated climate change concerns, structural dependency issues at the global level, and an increasingly disengaged and uneducated consumer population

CSA Motivations

Motivations associated with CSA farmer and shareholder membership engagement is often corollary to the list of concerns and/or traits associated with conventional agriculture noted above. That is, that participation in CSA is commonly a response to a set of values and beliefs that are motivated by some level of ecological, sociocultural, and/or political-economic concerns – what Russell and Zepeda (2008) in their study of the Troy Community Farm in the United States refer to as intrinsic properties. These include “. . . not only the quality (freshness and flavor) of the produce itself, but the interactions the consumers have with the farm and CSA community and the sense of well-being or moral satisfaction that comes from supporting a system that consumers believe is good for the environment, their health and the health of their community” (p. 136). Re-embedding and the decommodification of food are the kinds of terminology often associated with these values, with studies examining farmers and shareholders generally observing prioritization of motivations as follows (see Cone and Myhre 2000; Feagan and Henderson 2009):

- Healthy environment
- Organic produce
- Fresh produce
- Local food sources
- Knowledge of provenance and producers of food
- In-season food
- Health – personal and family
- Reduction in packaging
- “Community” relationship building in some form
- Price
- Some manner of events and celebrations

CSA Diversity and Attributes

CSA is distinctive in a variety of ways from other more conventional farming forms. CSA farm operations are generally smaller in size (7 acres on average [approx. 3 ha]) and are predominantly

organic and/or biodynamic oriented in their food production methods; the operator-farmers are on average 10 years younger than their conventional counterparts and generally less experienced; see a greater percentage of women operators; farmers and shareholders are predominantly white (non-Hispanic); and shareholders are more highly educated and in higher income categories than the average consumer (Cone and Myhre 2000).

There is a range of attributes commonly associated with CSA, though this range is increasing as this farming form shifts and adapts. The most common are those with reference to the variation in size of shareholder numbers, organizational orientation, production methods, categories of food offerings and services, food distribution methods, educational methods, participation system and practices, and others. For example, shareholder numbers vary from perhaps 10–200 (and much higher occasionally), and CSA generally focuses on agricultural produce like vegetables and fruits, though there are those which may also supply dairy and egg products, meat, honey, and value-added goods like pickled produce and preserves, and there are now also examples of marine CSA.

Some CSA traits that have emerged give rise to both academic and activist discussion and debate. For example, CSA organizational structure can be a difficult and sometimes contentious theme, as writings on operational experiences by DeLind (1999) who has researched CSA extensively helped to highlight. Decision-making themes include the use or not of a “core” member group and the choice of tasks this core group then takes on (see McFadden 2004 for shifts in the core orientation of CSA), of share prices and appropriate reflection of full costs, CSA land ownership or not, member obligations regarding farm activities and duties, access or not by differing socioeconomic groups and other social justice objectives, educational issues and goals, and the occurrence or not of celebration and special events on CSA, for example. These are often the central kinds of decision-making and operational themes raised around CSA operation.

CSA Case Studies

Case studies of CSA have raised the profile of some of the context factors – meaning site- or place-specific conditions and broadly construed influences that can shape CSA scope and character. These have become more important with regard to understanding and defining CSA in its emergence as a farming form beyond its early inception phase, as it is apparent that “... the idealism with which the early adopters set out is in practice extremely hard, if not impossible, to maintain whilst still having to operate within the wider context of a globalized and industrialized food system” (Charles 2011, p. 363). A selection of examples here serve to provide insights into both unique and specific CSA dimensions and simultaneously, the different paths CSA has developed in the last 10–20 years.

Commitment Issues of commitment level and the dynamic character of shareholder value orientation along with producer narratives on CSA aspirations are a continuing discussion in CSA experience and practice. Devon Acres Organic CSA with a roughly 20 shareholder average over its 20-year history, and a share comprised largely of vegetables (though meat, milk and eggs are available to buy separately), is a useful example in this regard. Feagan and Henderson (2009) used Devon Acres in Ontario, Canada, to explore the terminology of “instrumental” through to “functional” and “collaborative” support, in order to assess shareholder participation and commitment levels and the factors influencing these choices. This study drew attention to the kinds of on-the-ground pragmatics of CSA function and operation – both as a means to observe the contingencies of daily partnership issues, as well as to highlight some of the larger factors which shape individual CSA efforts within the prevailing industrial food system context. It is useful to note in this study that shareholder values generally shift over time and that in contrast to collaborative ideals, most relations between farmer and shareholders could be conceived as instrumental, with longer-term shareholder values and practices on this CSA tending

to functional and occasionally into collaborative in their orientation.

CSA in China The first CSA in mainland China – Little Donkey begun in 2008 and located in the northwest of Beijing as part of a university project there – highlights the role of dramatically changing socioeconomic conditions in that country. Such changing context is giving rise to a growing middle class whose concerns and “mistrust” around health and food are associated with an increasing perception of food production concerns in China broadly. This shift in consumer awareness in tandem with the lengthy history of what in effect can be observed as sustainable peasant agricultural traditions in China provided the conditions within which an acceptance of a CSA form of food provision was now possible (Shi et al. 2011). Other aspects of the unique context of this case study are those attached to the uncertainties of land tenure in China and of the unknowns associated with different levels of Chinese government support of such farming models. It is appropriate to keep in mind that this is just one CSA, with around 130 shareholders at the time of the study, in a highly populated country. Notable in this case study, in the sense of its utility for examining variations in cultural perspectives on CSA, are the differences in conceptual definitions. For instance, though “sustainable agriculture” is the term used in the study, the authors observe that the corresponding Chinese term “ecological urban agriculture” (p. 552) is only roughly equivalent, in that it is also considered to be “multifunctional,” and this incorporates aspects of agriculture that sustainable agriculture does not usually subsume in western writings on this topic.

Gender The theme of gender also has become a recognized and sometimes contentious theme in CSA experience. This theme, raised in works like that of Cone and Myhre (2000) and Wells and Gradwell (2001), for example, have examined CSA for its gendered constructs, using the language of caring motives and practices, commonly positioned as feminine values. These “caring” attributes are frequently situated in contrast to

those associated with conventional agriculture and perceived masculinized traits or values like control, competition, exploitation, and detachment. In this vein, it is notable that the proportion of males is much higher in conventional agricultural operations than that of CSA. Examination of CSA structure and operation through this lens suggests consideration regarding potential differences in the ways women develop relationships and connections, process information and manage power, and the roles and responsibilities that women assume around childcare. Though discussions regarding gender in CSA emerge variously from “essentialist,” “situated,” and “socialization” variants, such gendered points of departure help to raise the profile of questions about the longer-term goals and farming ethics of CSA as a process relative to conventional agriculture and as Wells and Gradwell claim, to the role of care ethics in Western philosophy more generally.

Place Another trait that some consider integral to CSA is its orientation or attachment to “place” (see neolocalism). In terms of context, place mirrors a range of site-specific attributes to which CSA is often tailored: soils, climatic and hence farming season duration, agricultural history, local community politics, key or inspirational entrepreneurial individual(s), etc., along with the objective of reducing the distance between consumers and producers more generally. This kind of place orientation trait is notable in the expression by those who see CSA as meaning: “a fundamental rethinking of the relationship among food, economics, and community, a move towards a greater degree of ecological sustainability and an attempt to partly disengage from the global supermarket and reestablish vital local agricultural economies” (Schnell 2007, p. 550). The common usage of terms like place, community, and locality in the discourses around CSA is indicative of how the provenance or geographic origin of food has become part of the place-positioning value that CSA attaches to its agricultural purpose and intentions. And this in turn is suggestive of the discussions regarding the decommodification of food through such alternative food provision

venues – that food value is not just determined by its price, for instance. In this vein, it is also discernible that CSA location is often relative to certain kinds of geographic parameters like those related to areas of higher population density – an urban orientation, higher-income areas, more predominantly white populations, and to some degree, to farming areas with a legacy of smaller agricultural operations. These conditions up to this juncture have fostered a greater incidence of CSA development (Schnell 2007).

Membership Learning Examination of motivations of shareholders and farmers on a CSA in Scotland helped to reveal the potential for elevated levels of understanding and education resulting from CSA membership and participation. What they discerned as “graduation” effects (see Cox et al. 2008) was about how participation in this kind of producer-consumer network affords potential for broadened understanding of various aspects of the conventional food system relative to the experience of this alternative agricultural system. It is appropriate however to point out that such graduation effects occur with those members who decide to continue membership and hence are more willing or able to learn and adapt. In contrast, non-continuing members expressed less interest and/or did not exhibit such graduation effects, perceiving CSA to demand adaptation and changes in practices and attitudes which were not part of their original intentions for participation.

CSA Concerns

A number of concerns have emerged since the inception of CSA, including a variety of on-the-ground realities associated with CSA structure and operation. These include such things as:

- “Self-exploitation” of farmers and an unequal sharing of risks
- Nonparticipation on the part of shareholders
- Inequities between farmers and shareholders
- “Local” and “localism” traits associated with CSA requiring more critical evaluation

- The need to understand and evaluate CSA more clearly with respect to its role as a process within, parallel to, complementary, and/or in contrast to the conventional food system
- Lack of understanding and/or misinformation about CSA character and aspirations
- CSA place with respect to concepts of “community” and models of social interaction, civic agriculture, etc.
- Changing structure and organizational elements behind CSA: seeking effective function and stability in the midst of food system change
- Membership attrition and turnover

For example, self-exploitation of farmers is observed when CSA producers are unable to ask for and receive compensation that is reflective of the full value of their contributions in labor and effort. Generally, this means that the farmers underprice or subsidize the shares in their CSA by not paying themselves adequately. Further, inequities between farmers and shareholders is common and is tied to the basic observation that the shareholders are generally middle to upper class, making substantially more money than the farmers of the CSAs to which they belong. If indeed CSA has some radical or oppositional long-term objectives relative to the conventional food system, then social inequalities located on-farm suggest the extent of work still to do in moving this objective out into the broader social order.

CSA Trends: Future Directions?

Original CSA ideals have seen many changes over the almost 30 years since CSA inception in the United States (and since its earlier antecedents in Europe and Japan). This has meant some adaptation of the attributes around which it originally aspired, for instance, while still exhibiting both processes and objectives that respond to the range of concerns associated with conventional agriculture. Part of the adaptation process has been tailoring CSA practice to specific contexts as case study research has been useful in highlighting.

Specific emerging issues and responses include those of land tenure in the face of increasing costs of land and developing means by which to network through collaboration and cooperation among CSAs in close proximity to one another. Others would include means to address ways to be more inclusive and socially diverse while also ensuring that CSA efforts sustain farmers economically.

Further to these ideas, CSA research and exploration have spread into geographies where CSA is only just beginning to emerge. This includes areas like Southeast Asia, China, and so-called less-developed countries, whose “locals” are just as important as the *local* around which much CSA development in the north is associated. Continued work in CSA can also benefit from better understanding of motivational characteristics of membership and such things as potential adaptation and behavior change that can ensue from participation – by both shareholders and the farmer-producers involved.

Further work and understanding of the influence of context or situation would also provide both a sense of the realities and pragmatics behind such alternative agricultural efforts, as well as a sense of how the broadly accepted values, principles, and practices of CSA can be effectively adapted to place. Recent research on the development of CSA in China can provide some useful insights on situational and values ‘context’ attributes for example, that is unique to the largely western character of CSA examination and practice so far. And if CSA is to manifest some of the kinds of long-term outcomes contained in its alternative or oppositional role to conventional agriculture, then efforts to address member attrition rates through the development of both more effective communication between farmers and shareholders, and its corollary regarding learning about CSA, would be appropriate work towards increased longevity of membership. Finally, recognition of the still minor overall contributions that CSA makes with respect to the dominant conventional food system would be an appropriate context to which further research and implementation efforts could be situated or directed.

Summary

This entry has provided a survey understanding of CSA – community-supported agriculture – by defining its basic contours, some notes on its history and development, on its broadly shared characteristics, as well as the role of various context factors which influence and shape CSA in place. This included some observations regarding ongoing concerns and trends. Though development and differentiation over time is an important aspect of current and likely future CSA, it is apparent that the growth and interest in CSA as an alternative farming system or network within or parallel to the conventional agricultural system, by both consumers and producers, is a dominant attribute associated with this form of farming.

Company image of food business; Food industry and communication with stakeholders; Representation of food industry

Introduction

Large-scale organizations have to respond actively to the growing competition on the economic market. One of the ways for companies to be recognized as trustful and competitive business entities is to create a strong company identity that is highly valued by workers and stakeholders. This issue proves to be especially important in the food industry, which has to provide products and services meeting various needs and expectations simultaneously, such as nutrition, value for money, as well as security and safety. To take a broad perspective of the issue that allows for creating and maintaining the effective identity of companies representing food industry, all sensual dimensions have to be examined, paying attention to spheres of cognition.

Defining the Term *Company Identity in the Food Industry*

Company identity is understood as the sum of components shaping both corporate and organizational identity. These two concepts have both similarities and differences as far as the target audience and communication channels are

concerned. Corporate identity is directed at external stakeholders and their perception, whereas organizational identity concentrates on the internal sphere, for example, the way a company is viewed by its employees (Whetten and Goldfrey 1998). Additionally, corporate identity is related to the visual aspect of company's life (Whetten and Goldfrey 1998), whereas organizational identity is more concentrated on the verbal representation (Hatch and Schultz 2000). Thus, the notion of company identity encompasses various methods of analyzing social personae at the level of business entity and takes into account both its internal and external dimensions. It should be noticed that the concept of company identity is often not observed in the course of everyday activities and standard performance, but it is rather addressed when some uncertainty appears, regarding such issues as occupation, company, or person (Alvesson 2007).

Moreover, it is often called upon in the moments of change, crisis, or risk when the common values and norms are supposed to help face some new issues. Company identity serves various functions at both the internal and external levels. Company identity is important since it determines the way customers perceive the offered products. Internally, it gives some guidance for its employees regarding the values esteemed by the organization they work for. Additionally, company identity is visible not only in the companies with established positions on the market but also in the nascent ventures that seek investors since entrepreneurs are interested in information how the brand is perceived (Bielenia-Grajewska 2012a).

Multidimensionality of Company Identity

The concept of company identity encompasses various spheres since companies operate in changing legal, social, and cultural realities. The mentioned fluidity can be observed at both the individual and group levels, by analyzing how both worker's and company's personae have to respond to the alternating environment. Additionally, the way one perceives organizations

depends on the sensual dimensions of company representation and how different senses are engaged in creating and maintaining company identity. Thus, both the environmental factors encompassing, among others, law, society, and culture and the sensual tenets connected with human apprehension and cognition determine the creation and perception of companies operating in the food industry.

Legal Aspects of Company Identity

Companies operate within a legal environment. Each country has laws governing the performance of the food industry. For example, on the US market, the guide entitled *Guidance for Industry: A Food Labeling Guide* issued by the Food and Drug Administration specifies, among others, the use of information panel, size of letters, and necessary data on producers' name and address that should be available to customers. In New Zealand, there are four acts governing the safety of food: Food Act 1981, Animal Products Act 1999, Agricultural Compounds and Veterinary Medicines Act 1997, as well as Wine Act 2003. Moreover, the legal aspect of the food industry is also of interest to producers of food who are active in shaping the legal sphere of the food industry. One of the reasons for their engagement in food legislation is to create and maintain the competitiveness in the food industry and enhance the trust of customers in their products.

Social Aspects of Company Identity

Food companies serve various functions in a society. For example, the way a food company is presented takes into account the notion of social responsibility. The corporate social responsibility (CSR) policy in the alimentation sector is broad and diverse, concerning various issues and encompassing not only the users (customers) but also the environment the food comes from. As a result, some food manufacturers stress the ecological aspect of food manufacturing, e.g., by

stating that during the process of production, they use renewable energy or environment-friendly ingredients. One of the notions often stressed in the food industry communication is the issue of food safety that entails, e.g., the protection against microbiological risks such as bacteria and viruses, toxicological risks regarding chemical substances, and other nutrition risks (Deblonde et al. 2007). Thus, such topics as guarantee, security, certification, and control are often handled in corporate communication taking place in the food industry.

A related notion in the identity of a food company is the role of regional community in manufacturing alimentation. Thus, food producers might highlight, for example, the engagement of local farmers and workers in food preparation or accentuate the appreciation for natural surroundings where the company operates. Another notion is the proper treatment of subordinates and the respect of employee rights. It entails the recognition of workers' cultural and linguistic identities. As a result, the companies that respect workers' linguistic identity can form their common company image based on appreciation and trust that stimulates company's effectiveness and competitiveness, both on the internal and external levels (Bielenia-Grajewska 2012b).

CSR can also be related to quality through the proper selection of animals or plants for the preparation of food, and avoidance of using artificial substances or additives. Apart from the product-oriented CSR policy is the process approach to food production. The producers concern themselves not only with the final outcome but also with the processes involved in food manufacturing.

Cultural Aspects of Company Identity

People choose food products that are congruent with their system of virtues and their personal characteristics. When the product or the company violates one's code of values, then a person might not opt for the company and its products (Paasovaara et al. 2012). The same applies to

respecting religious beliefs and dietary preferences in advertising, offering, and serving food.

As far as the price factor is concerned, an individual's financial situation and the perception of quality and price ratio vary. Thus, customers judge that food is cheap, expensive, or good value for money according to their personal income, individual preferences, and shopping habits. Another aspect taken into account by food companies is mood and its implication for food selection. Food is also used to stimulate social situations because it may enhance meetings with other people. Moreover, since alimentation may influence other spheres of life, companies might call attention to how they revolutionize one's cooking habits by introducing new ways of preparing dishes that make cooking more pleasant, easier, and quicker.

As far as the notion of food portability is concerned, since people use products in different moments of their life, companies often stress the size or ease of transporting various comestibles. Another issue is the convenience of packaging, including the easiness of (re)opening or (re)closing the container with food as well as its thermal features related to food storing. Food producers stress that the merchandise they offer is low in calories, fat, gluten, sugar, etc. The other aspect is the type of meal the food is selected for since various products are consumed in many cultures at different times of the day. For example, biscuits or cakes may constitute the breakfast in some countries, whereas in the other ones they belong to the group of snacks. Thus, cultural preference should be taken into account when the food product is advertised in order to reach the target audience.

Sensual Dimensions of Company Identity

Since all of the senses influence food selection and consumption, companies will rely on the visual, verbal, auditory, olfactory, and tactile experiences of their customers and stakeholders. The simultaneous appeal to different senses may strengthen the identity of companies and stimulate customer

preferences as well as the subsequent food selection and consumption.

Visual Dimension of Company Identity

The visual aspects of company identity are mainly represented in such elements as logos, packaging, websites, or promotional materials. Among various visual tools, color plays a very important role since the use of color is supposed to evoke certain emotions and reactions. For example, since black is often associated with luxury, specialty, and individuality, it is used to advertise commodities that are expensive or directed at customers searching for individual and special merchandise. Green, on the other hand, is selected for products that are ecological, natural, and sustainable. Color is also employed to associate the offered food with some emotion it should evoke; for example, red symbolizes love and passion, whereas blue denotes relaxation.

The choice of visual tools selected for advertising the food company and its products depends on the aim of advertisements or corporate materials. For example, the food company rather opts for calm colors if it aims to stress its social or ecological activities taking place within standard business performance. However, the food producers select bright shades if they want to be viewed as dynamic or if they want to appeal to young consumers.

The other issue is the representation of group and community in food advertising. Food products can serve various functions in one's social life, e.g., they can be used in the moments dedicated to intimacy or companionship. Moreover, comradeship may stimulate food consumption; in some studies it is shown that due to the process of social facilitation, people eat more when they are in company. Thus, the motif of group participation is also applied to advertising, showing that consuming is a social and pleasurable activity. In addition, sometimes producers stress that even people who are allergic to some substances or follow a gluten-free diet can enjoy meals due to the elimination of these undesirable ingredients.

The size of containers or the meal itself also determines the food intake; if the portion is large, then people will eat more. In other studies it is stressed that the environment, such as the restaurant interior, may enhance food consumption (Stroebele and De Castro 2004). Thus, not only the food itself shapes food intake but also the surrounding (the design of shops, restaurants, or bars) determines customer preferences. Since the food coldness or heat stimulates hunger, appetite, and food preference and determines the amount of food intake, the issue of temperature is taken into account in creating corporate materials (Stroebele and De Castro 2004). This feature is also visible in the way food companies advertise their products. Meals that are supposed to be served hot are shown with some smoke or in the process of being cooked.

Additionally, the temperature of food is often linked to the functions it should serve, for example, hot tea for warming up and cold tea for cooling off. However, it should be remembered that the issue of food temperature should be viewed through the perspective of cultural differences since individuals' expectations regarding the temperature of meals vary depending on their culinary habits. The same applies to various kitchen utensils or equipment used in advertising food products. The selection of cutlery or crockery in picturing food depends on the target group the product is directed at.

In the case of beverages, cloudiness is an issue that might be stressed. For example, wines or beers are expected to be clear, whereas cider is expected to be cloudy. The other notion is glossiness that mirrors the light reflectance of such products as cakes, apples, etc. The next aspect of color is connected with the intensity of some color related to food processing. Thus, products that are baked or cooked should possess the type of color that is usually associated by customers with the merchandise of that type (Lawless and Heymann 2010).

Verbal Dimension of Company Identity

The verbal dimension of food company identity can be observed at word, sentence, or story levels.

Looking at the issue of verbal identity from the word perspective, the name of the company, being often the name or the surname of the founder, serves as the guarantee of tradition and quality. When the brand is the name of the person, the advert is often accompanied by a narrative, which explains how the company originated and how long it has been present on the market. To add, the length of words influence customer preferences and descriptive names determine post-consumption evaluations. Consequently, the dishes having longer and elaborative names are often classified as tastier or more appealing than similar products with short names (Wansink et al. 2005).
